## Sludge samples from Fook's lode, Waratah

*by G. B. Everard*

Sludge samples taken from various depths between 450' and 559' in DDH F1 at Fook's lode, Waratah, were examined under the microscope. These samples were from an area of poor core recovery which may have been mineralised.

The samples were all very similar and contained magnetic particles, rock fragments, clay material, quartz and feldspar, ferromagnesian minerals, calcite, fluorite and pyrite. No particles were positively identified as cassiterite.
