

The method adopted of combined high quality reflection shooting and refraction probes was successful in resolving the question of presence or absence of Latrobe Complex rocks and reliably delineated the structure on the horizons mapped.

The reflection sections show that as the Latrobe Complex thins to the west its older units onlap Basement. In this situation stratigraphic traps within the Latrobe Complex are possible. However, before they can be located a detailed study of the probable lithology of these rocks within the area will have to be undertaken. It is recommended that such a study be undertaken and when completed be related to the results herein contained.
