# 1 INTRODUCTION

The SS04 Survey recorded T/36P consisted of 16 lines totalling 680kms. These lines in-filled the existing 2D data that was reprocessed during the 3<sup>rd</sup> quarter 2004. Processing began in February and was completed in July 2005.

The SS04 Survey, acquired with a longer cable has different geometry from the Repro.. Processing parameters and sequence, though quite similar to the Repro. were tested to confirm they are suitable for this geometry. Lines nominated by Santos for testing are SS04-006 and SS04-009.

## 1.2 LOCATION MAP

## 2 PARAMETER TESTING

Lines nominated by Santos for testing :  
SS04-006 and SS04-009

The following table provides the list of tests performed:

| <i>Description</i>                           | <i>Format</i>       |
|--|---------------------|
| Raw displays                                 | Shot                |
| F-K analysis                                 | Shot                |
| Gain recovery                                | Shot                |
| FK filter                                    | Shot/Receiver/Stack |
| Linear Tau-P Noise Removal                   | Shot/Stack          |
| Tau-P Deconvolution                          | Shot/Stack          |
| Signature Deconvolution                      | Shot/Stack          |
| F-K and Radon demultiple                     | Gather/Stack        |
| Predictive deconvolution before stack        | Gather/Stack        |
| Pre stack migration velocity field smoothing | Velocity profile    |
| Pre stack migration aperture                 | Stack               |
| Stack mutes (outer and inner trace)          | Gather/Stack        |
| Pre stack scaling                            | Gather/Stack        |
| Predictive deconvolution after stack         | Stack               |
| Relative amplitude                           | Stack               |
| Zero Phasing                                 | Stack               |
| Post stack scaling                           | Stack               |

Parameter tests were presented as paper displays, or ftp'd to Santos in SEG Y format for evaluation on screen.

### 3 COMMENTS & CONCLUSION

The objectives of the survey are to delineate prospective targets previously identified from the reprocessing and to identify further opportunities within the Central and South West portions of the permit.

A symmetrical velocity (+/-2000m/s) filter was designed in the F-K domain to preserve the primary reflection signal and to discriminate against coherent dipping noise trains. NMO corrections were applied before filtering to preserve amplitudes of far offset primary data. In addition, linear noise removal in the Tau-P domain was applied to attenuate strong linear noise on the far offsets.

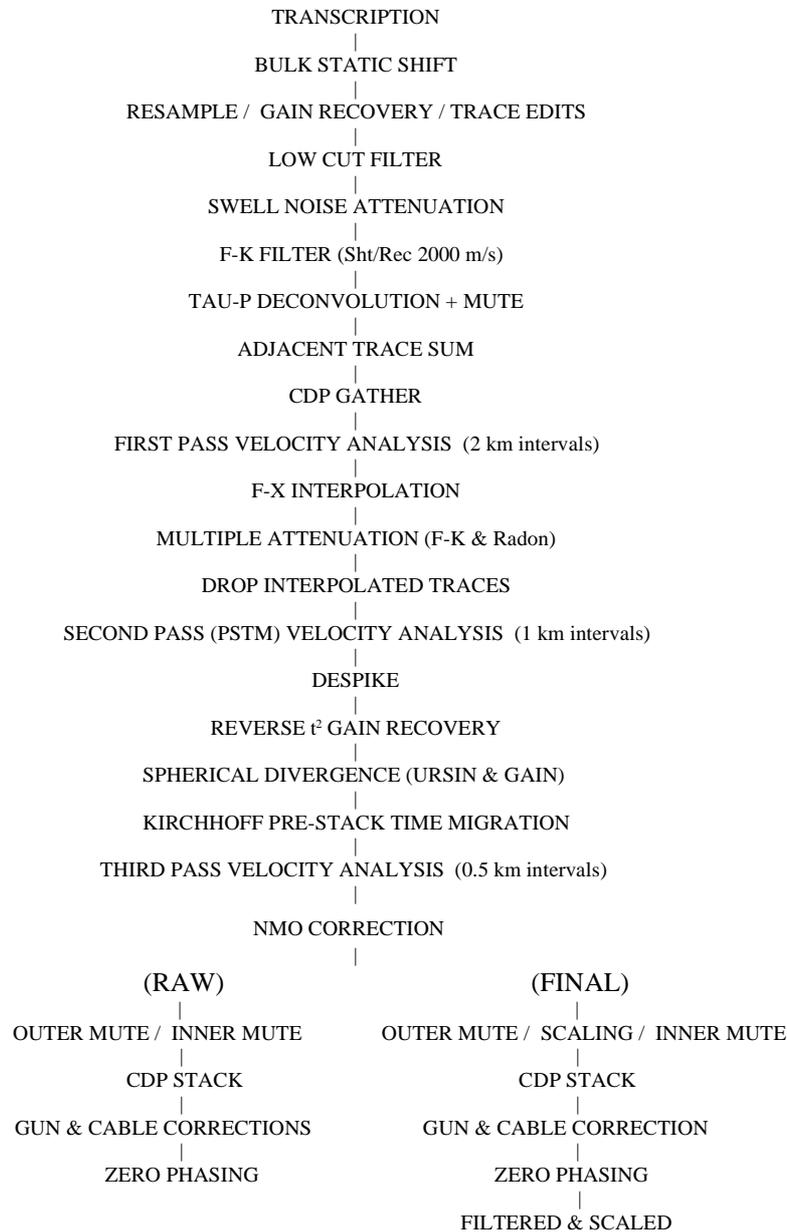

Multiple attenuation was achieved in two passes. Firstly the seafloor multiples were targeted using predictive deconvolution in the Tau-P domain. Gap length was set to follow the water depth, no wavelet shaping took place. Secondly the data was interpolated prior to RADON demultiple to reduce any aliasing in the CDP domain. Slow multiple energy was targeted in this pass using a 2km velocity field. F-K demultiple was also employed to target multiples in the shallow region where RADON does not handle effectively. Residual RADON was tested but only applied to the archive of the final PSTM gathers.

Pre-stack Kirchhoff time migration was used which collapsed all diffraction energy and more correctly positioned the data. This allowed for more accurate velocity analysis as the interference from diffraction and miss-positioned energy were eliminated.

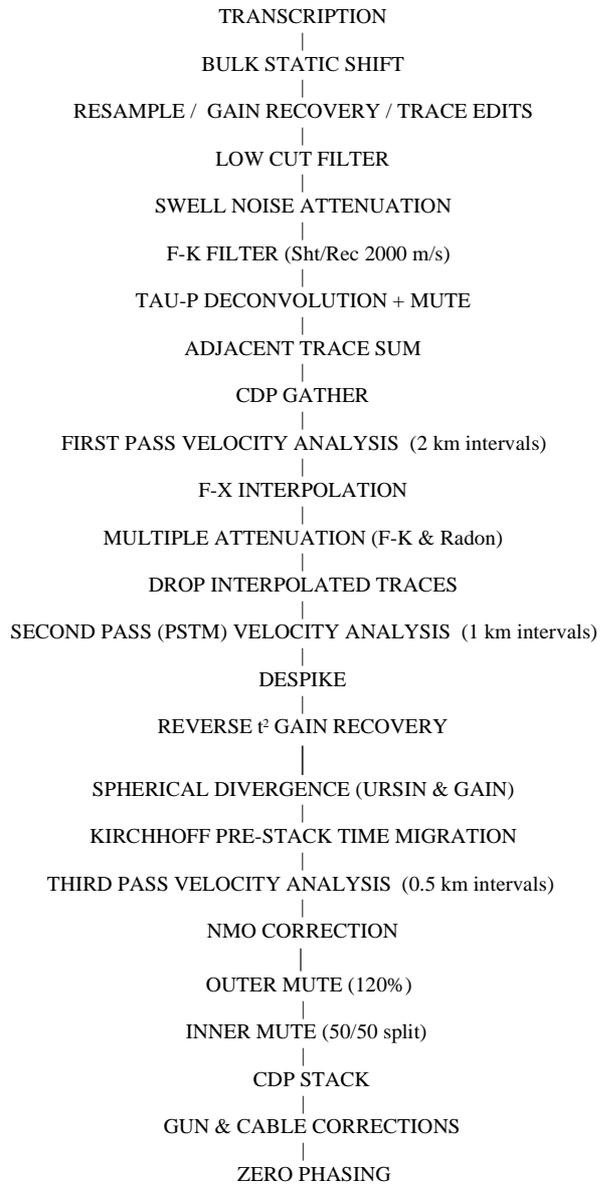

Final archived data were phase rotated by 180 degrees to show water bottom as trough which is consistent with the 2004 T/36P Repro..

# 4 PROCESSING SEQUENCE

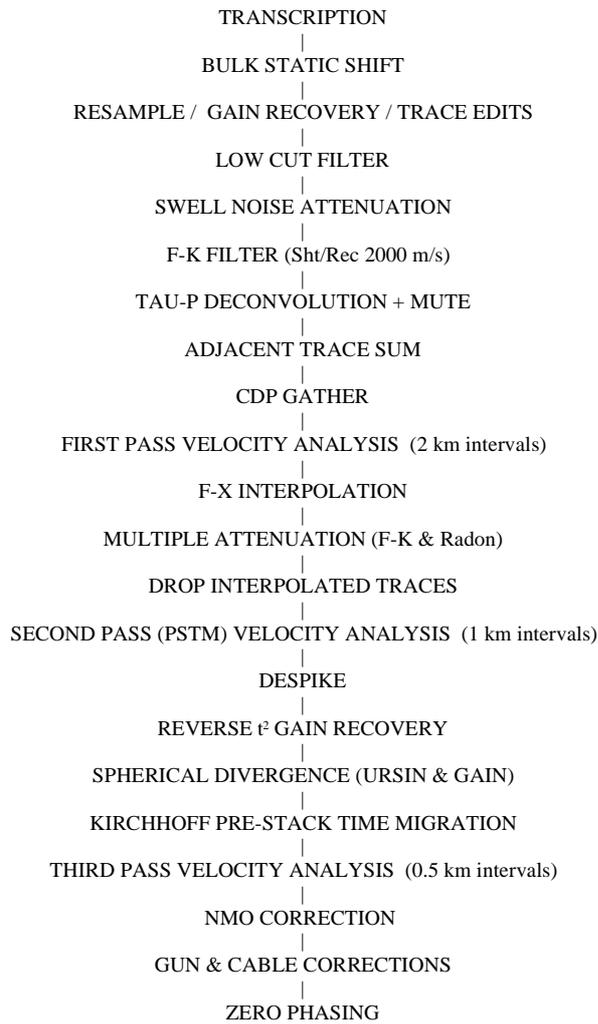

## 4.1 PSTM STACK (RAW AND FINAL)

## 4.2 PSTM NEAR & FAR ANGLE STACKS (RAW )

## 4.3 PSTM GATHERS

## **5 PROCESSING DESCRIPTION**

### **5.1 TRANSCRIPTION**

Field data were converted to F.S.I's internal format (UNISEIS) which is trace sequential with samples stored as 32 bit IEEE floating point. At intermediate processing stages the data are stored on disk in sixteen-bit integer with a gain ranging scalar for each trace.,

### **5.2 STATICS**

A -50ms static shift was applied to the data to compensate for the recording delay.

### **5.3 RESAMPLE**

Resampled from 2ms to a 4ms sample period.

### **5.4 GAIN RECOVERY**

A  $t^2$  gain correction was applied to the data as an initial approximate compensation for spherical spreading amplitude losses.

### **5.5 TRACE EDITS**

Noisy and bad traces were identified from both observers logs and near trace displays / shot displays, and were removed prior to further processing.

### **5.6 LOW-CUT FILTER**

A low-cut filter of 5/18 Hz/dB/Octave was applied.

### **5.7 SWELL NOISE ATTENUATION**

Swell noise attenuation is achieved by shaping the amplitude spectra of selected "swell noise affected" traces.

Analysis and attenuation are performed in the FX domain, processing one source position at a time. For analysis, the amplitude spectra are normalised, considering only the higher frequency range which is less influenced by swell noise. After normalisation the swell noise traces are recognised by their relatively high amplitude, low frequency component. The shallow portion of each shot record is muted before analysis, removing the high amplitude shallow reflections and direct arrivals.

The user nominates a frequency range for analysis, and for spectral scaling. Typically this frequency range is from 0 to 32 Hz. Scalars are calculated to shape the spectra of individual swell noise affected traces to the mean of the non swell noise affected traces. The scalars are fully applied from 0 to one half the defined frequency range, after which the scalars are tapered to zero application at the maximum defined frequency. No modification is made to other traces.

The mechanism of swell noise recognition is not influenced by change in source energy, or by systematic variation in trace amplitude levels. Shots not affected by swell noise will not present any traces for swell noise attenuation.

The swell noise attenuation is monitored by recording the number of channels flagged as being affected by swell noise.

After application of swell noise attenuation, some high frequency noise was evident on the shot records. These spikes were attenuated with a mild 'despike' process. Amplitudes were measured in windows of 80ms length. The matrix was composed of seven consecutive time windows across 39 adjacent channels. The amplitude of the centre window is compared to the rest of the matrix and the centre window is defined as containing a spike if the peak to median ratio is greater than 10, or if the centre window median value exhibits more than 5.5 units of standard deviation from the average median. Spike affected windows are scaled to the mean of the matrix.

Despike was only performed in deeper parts of the shot record – commencing at seafloor two way time plus 3 seconds on the nearest offset, and with despike start times following a  $1500\text{m}\cdot\text{s}^{-1}$  parabolic 'NMO' curve on longer offsets.

## 5.8 MULTI CHANNEL FILTER (SHOT & RECEIVER DOMAIN)

A symmetrical “velocity” filter was designed in the F-K domain to preserve the primary reflection signal and to discriminate against coherent dipping noise trains. The filter employs a cosine-squared taper from  $k = 0$  to the velocity intercept at each frequency. Filtering was applied in both the shot and receiver domains. The input data was conditioned with a 300ms AGC, and the scalars preserved for removal subsequent to the application of the F-K filter. A cut off velocity of  $\pm 2000$  m/sec was used for both the shot and receiver F-K in the filter design and NMO was applied before and removed after the filter.

## 5.9 TAU-P DECONVOLUTION

The data was transformed into the Tau-P domain using the linear transform. Transform limits of -2500ms to 4200ms at an increment of 10ms (671 ptraces) were used.

Predictive deconvolution was performed in Tau-P space to target water layer reverberations. Design windows varied according to the water bottom. A 360ms operator with gap length varied by  $w_b - 40\text{ms}$ .

Application of the Tau-P deconvolution varied according to the apparent seafloor slope. In areas of steep slope the deconvolution was only applied for water bottom times of less than 400ms and tapered off at 600ms.

## 5.10 TAU-P LINEAR NOISE REMOVAL

While in Tau-P space linear noise may be removed by the application of scaling of or muting sections of the transformed data that represent the noise energy. Careful design can preserve the long offset primary data from being attenuated. For these data the following mutes were applied.

### Water bottom 100ms

### 5.11 ADJACENT TRACE SUM

A 2:1 trace decimation was applied to the data after performing array simulation using a trace mix on NMO corrected shot records with first pass velocity function.

Summation details:

| <i>Vintage</i> | <i>Input Traces</i> | <i>Input Trace Interval</i> | <i>Output Traces</i> | <i>Output Trace Interval</i> |
|----------------|---------------------|-----------------------------|----------------------|------------------------------|
| <i>SS04</i>    | 480                 | 12.5m                       | 240                  | 25m                          |

Trace Mix Details:

| <i>Time (ms)</i> | <i>Trace Mix</i> | <i>Time (ms)</i> | <i>Trace Mix</i> | <i>Time (ms)</i> | <i>Trace Mix</i>  |
|------------------|------------------|------------------|------------------|------------------|-------------------|
| 0                | 1 - 2 - 1        | 3000             | 1 - 2 - 1        | 8000             | 1 - 2 - 3 - 2 - 1 |

### 5.12 CDP GATHER

Shot records were sorted into 120-fold common depth point gathers.

### 5.13 FIRST PASS VELOCITY ANALYSIS

First pass velocities were determined using F.S.I.'s "MGIVA" interactive velocity analysis program. Each velocity analysis comprised a semblance display, a 21 CDP stacked panel repeated 14 times with a suite of velocity functions, and a central CDP gather. The suite of functions were generated using 0%, +/-4 %, +/-8%, +/-12%, +/-18%, +/-24%, +/-30%, and +40% increments from a central velocity function. The central function was derived from a brute velocity that varied according to water depth.

The velocity analysis incorporated a map of all velocity locations, and the semblance display included functions from proximate lines. This enabled the velocities to be picked with knowledge of a real velocity trend. Velocity QC could be performed more effectively when discordant velocities could be recognised on the map.

## 5.14 F-X INTERPOLATION

Common channel domain trace interpolation was applied in order to increase the spatial sampling and thus minimise any resulting aliasing prior to demultiple. The fold was doubled. The interpolated traces were dropped after demultiple.

## 5.15 RADON MULTIPLE ATTENUATION

Attenuation of multiples was achieved by modelling and subtraction using a least squares, parabolic Radon transform. Normal moveout corrections were performed using the first pass velocities, and the CDP gathers transformed into the parabolic Tau-P domain. The segment of the Tau-P domain corresponding to primary reflections is muted, leaving the multiple energy to be transformed back into the T-X domain and subtracted from the original CDP gather.

|                              |   |
|------------------------------|---|
| <b>Reference offset</b>      | 6089m   |
| <b>Frequency range</b>       | 4-90 Hz   |
| <b>Minimum p</b>             | -1000 ( <i>parabolic moveout, Delta-t, at reference offset</i> )                        |
| <b>Maximum p</b>             | +3500   |
| <b>Number of p traces</b>    | 451   |
| <b>Multiple p cut</b>        | 0ms/200;1000ms/200;2000ms/75;8000ms/50  |
| <b>Demultiple start time</b> | Watbot 100ms starts 800ms<br>Watbot 1000ms starts 1300ms<br>Watbot 2000ms starts 2200ms |

## 5.16 FK MULTIPLE ATTENUATION

F-K demultiple was used to attenuate a strong multiple train evident in the near surface. Normal moveout correction was performed using the picked first pass velocities, slowed by the percentages listed below. When NMO corrections are performed with these slowed velocities the primary events are over corrected and show negative dip, and the multiples will have positive dip. After FK transform the multiples and primaries will appear in different quadrants. Multiple attenuation can then be effected by filtering the positive quadrant before applying the inverse transform. Full application of FK demultiple is listed below.

Velocity reduction:

| <b>Time (ms)</b> | <b>Velocity %</b> |
|------------------|-------------------|
| 0                | 94                |
| 800              | 94                |
| 3500             | 90                |
| 8000             | 85                |

Full application of FK demultiple:

| <b>Water bottom (ms)</b> | <b>Full application</b> |
|--------------------------|-------------------------|
| 100                      | 800 ms                  |
| 1000                     | 1300ms                  |

| <i>Water bottom (ms)</i> | <i>Full application</i> |
|--------------------------|-------------------------|
| 2000                     | 2200ms                  |

Application times are with respect to gathers without NMO corrections.

A 300ms AGC was applied before the FK transform, and the scalars preserved for later removal. All interpolated traces were dropped after demultiple.

## 5.17 SECOND PASS VELOCITY ANALYSIS

Second pass velocity analysis was performed on Pre-stack migrated gathers. The first pass velocity field was used as centre functions for F.S.I.'s interactive velocity analysis package, MGIVA.

Analysis was performed at 1 km intervals. A suite of 14 pre computed stack panels were displayed with +0%, +/-3%, +/-6%, +/-10%, +/-15%, +/-20%, +/-25% and +/-30% velocity variation from the central function. The MGIVA velocity analysis is a 'map driven' package, where the user can instantly see modifications to the velocity field in map or section view. Neighbouring velocity functions are superimposed on the current location for easy recognition of velocity trends. Velocity interpretation is performed on the pre-computed stack suite, or on a colour contoured semblance display. Semblance interpretation is assisted with markers illustrating the position of potential water layer peg-leg multiples, and with an interval velocity curve.

## 5.18 DESPIKE

Despike was performed on all data. Amplitudes were measured in a matrix of time windows of 80ms length. The matrix was composed of seven consecutive time windows across 39 adjacent channels. The amplitude of the centre window is compared to the rest of the matrix and the centre window is defined as containing a spike if the peak to median ratio is greater than 10, or if the centre window median value exhibits more than 5.5 units of standard deviation from the average median. Spike affected windows are scaled to the mean of the matrix.

## 5.19 REVERSING OF GAIN RECOVERY

The  $t^2$  gain correction applied in section 5.4 to compensate for spherical spreading amplitude losses was reversed for both vintages.

## 5.20 SPHERICAL DIVERGENCE (URSIN & GAIN)

With the previously applied  $t^2$  gain function removed, it was then replaced with an offset and velocity dependent spherical divergence approximation as described by Bjorn Ursin (GEOPHYSICS Vol.55 No.4, pp492-496 1990).

Where  $T_0$  is the two way travel time,  $V$  is the RMS velocity at  $T_0$ , and  $V_0$  is the velocity in the first layer. Although this method is applicable to uncorrected data as a moveout tracking divergence correction, for algorithmic ease it is applied to NMO corrected CDP gathers.

$$\sqrt{\frac{T_0 \times V^4}{V_0^2} + (2 \times (\frac{V}{V_0})^2 - 1) \times X^2 + \frac{X^4 \times (\frac{1}{V_0^2} - \frac{1}{V^2})}{t_0^2}}$$

## 5.21 KIRCHHOFF PRE STACK MIGRATION

Full Pre-Stack Kirchhoff migration was applied using the azimuth cognizant migration algorithm in straight ray mode, with a 7500m half aperture. Apertures were muted with a 50% stretch mute to avoid operator aliasing. The velocity field was constructed by smoothing the second pass velocities. Migration was performed on all offset planes.

## 5.22 THIRD PASS VELOCITY ANALYSIS

The third pass velocity analysis was performed on the Pre-stack migrated gathers. The second pass velocity field was used as centre functions for F.S.I.'s interactive velocity analysis package, MGIVA.

Analysis were performed at 500m intervals. A suite of 14 pre computed stack panels were displayed with +0%, +/-2%, +/-4%, +/-6%, +9%, +/-12%, +/-15% and +/-20% velocity variation from the central function.

With 4<sup>th</sup> order NMO applied, the long offset data was not fully flattened. This was attributed to anisotropy in the over lying sediments. To correct for this Eta picking was conducted for every 2<sup>nd</sup> location (1km interval)

## 5.23 NMO CORRECTION

NMO correction was performed using the third pass (final) PSTM velocities with Eta corrections.

## 5.24 OUTER TRACE MUTE

A post NMO outer trace mute was applied to remove any coherent noise on the outer traces and to reduce contamination from the effect of NMO stretch on the far offsets. Muting parameters were spatially varied according to seafloor two way time.

### Watbot = 200ms;

Offset (m) 127 427 527 1127 6100

Time (ms) 150 150 350 1050 4350

### Watbot = 1000ms;

Offset (m) 127 927 1027 1227 6100

Time (ms) 900 900 1400 2000 4450

### Watbot = 1500ms;

Offset (m) 127 1027 1177 1427 6100

Time (ms) 1400 1400 1950 2300 4800

### Watbot = 2000ms;

Offset (m) 127 1077 1427 1777 6100

Time (ms) 1900 1900 2800 3200 5400

### Watbot = 2400ms;

Offset (m) 127 1127 1327 2527 6100

Time (ms) 2300 2300 3200 3900 5900

## 5.25 PRE-STACK SCALING

Amplitude balance was performed with a two window AGC with control over the strength of application.

|                       |                |
|-----------------------|----------------|
| <b>Window Lengths</b> | 400ms / 1200ms |
| <b>Equalisation</b>   | 60%            |

Note: Scaling was only applied to the Final Filtered and Scaled PSTM stack datasets. No pre-stack scaling was applied to the archived Raw PSTM stacks nor the gathers.

## 5.26 INNER TRACE MUTE

An inner trace mute was designed and applied for each vintage for two main reasons :

1. to remove any coherent noise on the outer traces and
2. to reduce contamination from the effect of NMO stretch on the far offsets.

Watbot = 200ms:

Offset (m) 127 827

Time (ms) 700 2100

Watbot = 1000ms:

Offset (m) 127 827

Time (ms) 2000 2800

Watbot = 1500ms:

Offset (m) 127 827

Time (ms) 2500 3400

Watbot = 2000ms:

Offset (m) 127 827

Time (ms) 2900 3900

Watbot = 2400ms:

Offset (m) 127 827

Time (ms) 3100 4000

## 5.27 CDP STACK

The traces within each CDP bin were summed using a  $1/\text{root}(N)$  stack compensation. The angle stacks were summed using  $1/N$  stack compensation.

## 5.28 GUN AND CABLE DEPTH CORRECTION

A static compensation for gun and cable depths was applied. The static value was calculated using average gun and cable depths supplied in the observer's reports. Static correction computed is 8ms.

## 5.29 CONVERSION TO ZERO PHASE

The data was converted from minimum phase data to zero phase, using the Weiner-Levinson double inversion method to derive an operator based on the amplitude spectrum. A 180 degree phase rotation was applied to the data so that the sea floor event appears as a trough.

### 5.30 FILTER

Unwanted noise that lay outside the frequency range of the desired reflection data was attenuated with application of a series of zero phase time variant filters. These filters employed cosine squared tapers between the limiting frequency pairs.

Water bottom = 100ms

| <i>Application time (ms)</i> | <i>Frequency limits (Hz)</i> |
|------------------------------|------------------------------|
| 1000                         | 6 / 10 – 60 \ 70             |
| 2000                         | 4 / 8 – 40 \ 50              |
| 3000                         | 4 / 6 – 30 \ 40              |
| 5000                         | 3 / 5 – 20 \ 30              |
| 6000                         | 3 / 5 – 15 \ 25              |

Water bottom = 2000ms

| <i>Application time (ms)</i> | <i>Frequency limits (Hz)</i> |
|------------------------------|------------------------------|
| 2000                         | 6 / 10 – 60 \ 70             |
| 3000                         | 4 / 8 – 40 \ 50              |
| 4000                         | 4 / 6 – 30 \ 40              |
| 6000                         | 3 / 5 – 20 \ 30              |
| 7000                         | 3 / 5 – 15 \ 25              |

### 5.31 POST STACK SCALING

Amplitude balance was performed with a two window AGC with control over the strength of application.

|                       |                |
|-----------------------|----------------|
| <i>Window Lengths</i> | 400ms / 1200ms |
| <b>Equalisation</b>   | 60%            |

Note: Scaling was only applied to the Final Filtered and Scaled PSTM stack datasets. No post-stack scaling was applied to the Raw PSTM stacks that were archived nor the gathers.

### 5.32 ANGLE STACKS

Using the full inner trace mute and 120% of the outer trace mutes, the remaining 'live' data was split 50% / 50% to produce near and far angle stacks on both the raw and the filtered/scaled PSTM data.

## 6 APPENDICES
