LIST OF APPENDICES

1. SUMMARY

645005

A considerable amount of work has been completed on the Beatrice Prospect (EL 6/98), the Lake Dora-Lake Spicer area (EL 24/96) and the West Sedgwick area (EL 6/98) of the Queenstown Project during the reporting period. The majority of effort was at the Beatrice Prospect where the following work was completed:

- Relogging of previous drill holes
- 1:1000 scale and 1:5000 scale mapping, compilation and geochemical sampling.
- A 580 sample MMI soil sampling programme.
- A pole-dipole induced polarisation survey.
- An orientation CSAMT survey.
- 4 diamond drill holes for 2392.6m.
- Downhole EM on the four drill holes.

Results from the work at Beatrice have been encouraging with wide intervals of highly anomalous zinc intersected in two of the four holes drilled (best results of 0.8m @ 8.77% Zn, 2.15% Pb, 105 ppm Ag from 459.3-460.1m in MS10 and 68.4m @ 0.49% Zn, 0.21% Pb and 7.8 g/t Ag from 515m- 583.4m in MS8).

Previous exploration completed at West Sedgwick has been compiled and reviewed. This included relogging of seven diamond drill holes for 2156m. The key horizon at the top of the CVC (and/or basal Tyndall Group) is under-explored in this area particularly in areas of extensive glacial cover. An exploration programme is proposed to test this contact during year 2 of the licence.

The Lake Spicer - Lake Dora area has been mapped in detail. Significant results have been returned from rock-chip sampling of old workings (up to 3.85% Cu, 2.1% Pb, 9.65% Zn, 49 g/t Au, 250 g/t Ag, and 2.2% Co; from different samples), however, the style of mineralisation (narrow veins) is less encouraging.

2. INTRODUCTION

The Queenstown North Project covers an area extending from just north of Queenstown to Mt Selina (Figure 1). The project was formed by the amalgamation of reporting and expenditure commitments for EL 24/96 Walford Peak, EL 6/98 Queenstown and EL 20/98 Lake Beatrice (Figure 2).

Work completed during the year has concentrated on three main areas; the Beatrice Prospect, the Lake Dora-Lake Spicer area and the West Sedgwick area.

The majority of effort was at the Beatrice Prospect where the following work was completed:

- Relogging of previous drill holes (1736m) and re-assaying of some core.
- 1:1000 scale and 1:5000 scale mapping, compilation and geochemical sampling.
- A 580 sample MMI soil sampling programme.
- A pole-dipole induced polarisation survey.
- An orientation CSAMT survey.
- 4 diamond drill holes for 2392.6m.
- Downhole EM on the four drill holes.

The Lake Spicer - Lake Dora area has been mapped in detail and some rockchips were collected during this exercise.

The previous exploration completed at West Sedgwick has been compiled and reviewed. This included relogging of seven diamond drill holes for 2156m. An exploration program has been proposed as a result of this review and this will commence in year 2 of the licence.

3. LAND TENURE

The Queenstown North Project comprises EL 24/96 Walford Peak, EL 6/98 Queenstown and EL 20/98 Lake Beatrice (Table 1). Permission for joint expenditure and technical reporting on these licences was granted on the 23rd March 1999.

EL 6/98 Queenstown comprises two blocks; the southern block is contiguous with EL 20/98, however, the northern Moxon Saddle block is isolated and abuts Pasminco's Tullah EL (22/90). Joint reporting for the Moxon Saddle block of EL 6/98 and the Tullah EL was approved in February 1998 and the reader is referred to the Tullah (EL 22/90) annual reports for results from this area.

It has been requested that two additional licences (EL 10/99 and 13/99; granted during 1999) be included in the project, for combined reporting and expenditure commitments, however, at the time of writing this has not been approved. No significant work was done on these two licences during the reporting period.

Table 1. Queenstown North Project; constituent Tenements.

Licence Number	Licence name	Date Granted	Area (Sq km)
EL 24/96	Walford Peak	26th November 1996	44
EL 6/98	Queenstown	30th January 1998	33
EL 20/98	Lake Beatrice	4th November 1998	10.47
EL 10/99	Lake Margaret	27th July 1999	5
EL 13/99	Linda	12th July 1999	6.5

4. REGIONAL GEOLOGY

Three VHMS prospective geological environments occur around a core of Owen Conglomerate forming the West Coast Range in the area covered by the Queenstown North Project (Figure 3; derived from the published 1:25,000 scale government geology maps). These environments are the Walford Peak area on the eastern flank of the range, the West Sedgwick area on the western flank of the range and the Beatrice area on the northern flanks of the Comstock Valley that cuts through the range.

Walford Peak

The Regional Geology of this area has been described in detail by Weber et al.,. (1997). The eastern edge of the Walford Peak area comprises Precambrian Tyennan basement, a metamorphic terrain described as mainly lower greenschist facies phyllites and quartzites. This basement is unconformably overlain by elements of the Cambrian Mt Read Belt comprising the Sticht Range Beds and correlates of the Tyndall Group. To the west, and overlying the Tyndall Group correlates, are the siliciclastic Cambro-Ordovician Owen Conglomerates. The contact between the Tyndall Group and Owen Conglomerate is variable and may be conformable and gradational, unconformable or faulted.

The middle Cambrian Sticht Range Beds comprise sediments from pebble-cobble conglomerates to siltstones and minor black shales (with a largely metasedimentary provenance) and minor volcaniclastic units. There is an apparent gradational relationship between the Sticht Range Beds and the overlying Tyndall Group.

The Tyndall Group comprises a volcanic conglomerate unit (the Dora and Selina conglomerates) underlain by quartz phyric lavas, intrusives and volcaniclastics. In the northern part of the area the Tyndall Group volcanics are intruded by the Murchison granite, a Cambrian intrusive complex about 7.5 km long and 3 km wide.

West Sedgwick

The western part of the West Sedgwick area is dominated by mixed volcaniclastics and sediments of the Yolande River sequence that have been intruded by felsic-mafic porphyries. The eastern part of the area is dominated by feldspar±hornblende-phyric volcanics of the Central Volcanic Complex. The volcanics contain dacitic lavas and volcaniclastics typical of the Central Volcanic Complex and also contains abundant variably magnetic, andesitic (feldspar-hornblende-phyric) hyaloclastite lavas and subvolcanic intrusions. The andesitic volcanics are similar to the Anthony Road Andesite occurring 10 km to the north. Several black shale horizons occur within this package and these have generated good IP anomalies.

The Central Volcanic Complex is overlain by Tyndall Group rocks at Zig Zag Hill and also 8 km north in the Basin Lake area. It is probable that there is a continuous thin sliver of Tyndall

Group between the top of the Central Volcanic Complex and the Great Lyell Fault for the length of the contact, although this contact is partly obscured by glacial deposits of variable thickness, see below. To the east of the Great Lyell Fault (GLF) the Owen Conglomerate is exposed. In the Zig Zag Hill area there are some structural complexities associated with the north-south Great Lyell Fault and east-west cross structures.

In the northern part of the West Sedgwick the Cambrian geology is obscured by glacial deposits. The glacial deposits are dominated by two major moraines. The largest is the 1.3 km long Hamilton Moraine, the second moraine occurs on the 800m long east-west ridge south of the Lake Margaret pipeline.

Beatrice

The geology of the Beatrice area has been described in detail by Boyd (1994). The Beatrice area lies on the steep southern slopes of Mt Sedgwick where the prospective volcanics are exposed in a window through the Owen Conglomerate formed by the valleys of Itat and Porphyry Creeks. Lavas, volcaniclastics and a black shale unit striking N-S are interpreted on published maps (Corbett and Jackson, 1987) as being CVC correlates. A large quartz feldspar porphyry sill (or series of sills) intrudes these rocks. These units are unconformably overlain by volcanic sandstones and conglomerates of the Tyndall Group and the Cambro-Ordovician Owen Conglomerate.

The top of Mt Sedgwick is columnar jointed Jurassic Dolerite interpreted as a remnant of a dolerite sheet (The lack of a strong magnetic signature suggests it is not a plug) that intrudes Permian tillite, which is exposed on the SE flank of the Mountain.

5. PREVIOUS EXPLORATION

5.1 Beatrice Prospect

Work has been completed at the Beatrice Prospect by The Mt Lyell Mining and Railway Company, Goldfields, BHP and RGC in the twenty three years since discovery of the prospect.

Mount Lyell Mining and Railway Company:

1975: The first mention of the Beatrice Prospect is in the **1976** Mt Lyell Mining and Railway Company (MLMRC) Annual Report (Brophy, 1976) where stream sediment sampling and follow-up mapping and sampling in the Itat Creek area is reported.

Stream sediment samples SS43 and SS44 collected in Itat Creek assayed 1110 ppm Pb and 1130 ppm Zn and 906 ppm Pb and 780 ppm Zn respectively. One rock chip sample of black shale assayed 375 ppm Cu, 1300 ppm Pb and 3,000 ppm Zn.

1976: During the 1976/77 field season exploration by MLMRC centred on the Beatrice Prospect (Walter, 1977). 43.5 kilometres of grids were cut, the grid was mapped, 'C' horizon soil samples collected at 30m spacings and a gradient array IP survey was completed over 38 line kilometres of the grid. In January 1976 MLMRC joint ventured EL 10/69 with Getty Oil Development Company Ltd (GODL).

1977: During 1977/78 (Hutton, 1978) an extra 4 kilometres of lines were cut. The western part of the grid (lines 00N-1600N, from their western ends to approximately 400m east of Itat Creek) were -80# soil sampled and assayed for Cu, Pb, Zn, Ag and Mn. The sampling interval was 30m with intermediate 15m sampling over IP anomalies.

A major geochemical anomaly was detected between lines 08N and 16N (open to the north) that corresponded with a SW trending black shale unit and altered tuff. Best values were 510ppm Cu, 1.1% Pb, 1900 ppm Zn, 6 ppm Ag and very high Mn (up to 15.5%).

1978: During **1978-79** the above mentioned geochemistry anomaly became known as the Mt Sedgwick Anomaly Zone (MSAZ) and the entire gridded area was referred to as the Beatrice grid (Hutton, in Reid et.al 1979).

An access track was excavated into the prospect with both a western track, which required blasting (near MS-3) and an eastern track. Mineralisation was recognised in both these roads. This western track was rock chipped at 5m sampling intervals.

The entire 80m assayed 80m @ 0.34% Zn, 0.22% Pb, 65 ppm Cu and 3.7 ppm Ag. The best interval assayed 5m @ 0.57% Zn, 0.63% Pb 90 ppm Cu and 9 ppm Ag. Eleven samples were collected from the eastern road. These samples averaged 1.60% Zn, 1.28% Pb, 250 ppm Cu and 6 ppm Ag. Hutton (in Reid et.al., 1979) states that these results are not representative of the entire section and that if this section was sampled methodically similar results to the western road would be achieved.

Lines 1800 and 2000N were soil sampled and the MSAZ was shown to continue giving it a strike length of +1200m and a maximum width of about 300m. By line 2000N the Zn anomaly appears to be petering out whereas the Pb anomaly is still wide and strongly anomalous.

109 rock chips were collected and assayed for Cu, Pb, Zn, Ag, Mn, ± S, Au, Fe, Co. Only eight samples were analysed for gold and these all assayed <0.9 g/t Au. Best base metal results were:
9% Zn, 0.19% Pb, 0.07% Cu and 7 g/t Ag and
1.9% Zn, 5.7% Pb, 0.025% Cu, 12 g/t Ag and 0.5 g/t Au.

Three diamond drill holes, designed to test the MSAZ between 1400 and 1600N, were completed by Associated Diamond Drilling. DDH MS1 (329.1m) was drilled from east to west and intersected 7m @ 1.1% Pb, 1.7% Zn, 7 ppm Ag, 0.3 ppm Au from 62-69m and 2m @ 0.14% Cu, 2.7% Pb, 5.1% Zn and 22 ppm Ag from 111-113m. Bedding is steeply west dipping and this hole therefore largely drilled down bedding. DDH MS2 (301m) was drilled from west to east and only intersected low grade mineralisation; the best intersection being 17.25m @ 0.3% Pb, 0.54% Zn and 5 ppm Ag from 62-79.25m. DDH MS3 (328m) was drilled to test beneath the good rock chip results from the western and eastern access tracks. The best intersections were 7m @ 0.4% Pb, 0.58% Zn and 4.5 ppm Ag from 111.6-118.6m and 15m @ 0.4% Pb, 0.6% Zn and 4 ppm Ag from 170-185m.

The following geophysical surveys were completed by Scintrex: EIP gradient array, Downhole three-array, Schlumberger Array, Dipole-dipole and pole-dipole surveys.

1979: During 1978-79 (Meares, 1980) drill holes MS4 and MS5 were completed and 1065 soil samples were collected.

DDH MS 4 (350m) was collared to test northern extensions to mineralisation encountered in MS 1 and in the road exposures. Assay results were disappointing with a best result of 6m @ 0.3% Pb, 0.7% Zn, 2.7 ppm Ag and 0.3 ppm Au from 144-150 meters. The hole was drilled to the west and, as with MS 1, it largely drilled down bedding.

Drill hole MS 5 was drilled to determine the cause of a chargeability anomaly associated with the quartz-feldspar porphyry. This hole intersected black shales at 39.6-62.4 and 105.8-139 meters. The black shales were interpreted to explain the IP anomaly and the hole was terminated. No significant mineralisation was intersected.

The eastern portion of the grid was soil sampled (east of 386000 mE) with 1065 C horizon -80# soil samples. Samples were collected at 30m centres.

Geophysical surveys carried out on the grid during the 1978-79 field season included; Ground magnetics, Gradient array IP, Pole -dipole IP and Dipole-dipole IP.

Goldfields

1983: There was no further work done at Beatrice until 1983 when Goldfields Exploration (the exploration division of RGC and MLMRC) was required to relinquish 50% of EL 9/66. To aid this a geological review of the ground was completed (Purvis, et.al 1983). Major conclusions were that the geology at Beatrice was regarded as being similar to Red Hills and that previous drilling was not an adequate test of the MSAZ, as holes were drilled at a low angle to dip and strike (MS 1 and MS 4) or were collared underneath the shales (MS2 and MS3). Although these comments are not disputed the four holes are a reasonable test of the soil anomaly and wisdom in hindsight is always very easy.

The review team recognised two areas of potential for mineralisation:
1. Steeply dipping mineralised shale in Itat Creek,
2. Extensions of the shale and ashes-shales-ignimbrites underlying the Mt Sedgwick Porphyry to the East and West of Itat Creek.

15 rock chip samples were collected by the review team, three of these assayed >1000 ppm Zn and > 400 ppm Pb, however, all samples were below detection in gold. The validity of the original gold assays were strongly queried (note: Goldfields base metal assays also appear to be low for the Beatrice Prospect and recent work (section 6.1.2) shows unequivocally that the basemetal mineralisation may be Au-rich). No further work was done on the Beatrice Prospect and the ground containing the prospect was relinquished in by MLMRC in 1987; the area was picked up by BHP as part of EL 103/87.

BHP

1989: The Beatrice Prospect remained unexplored until 1989. BHP remapped the area, relogged drill holes MS1-MS5 and conducted a four loop UTEM survey (Wilde and Kerr 1990). No strong conductors were associated with the base metal mineralised zone on the Beatrice grid and only poorly conducting features, related

to structures or lithologics, were recognised. In 1991 RGC Exploration joint ventured into the property with BHP.

RGC

1994: In 1994 the prospect was revisited by RGC Exploration (Boyd, 1994). A literature review was completed, the grid was remapped in detail and drill core was relogged. The main aim of the remapping was to determine if the black shale continued south past the limit of previous drilling. This aim is rather peculiar as it had been determined in 1978 that the black shales continued south of the known mineralisation (Reid et al., 1979). This remapping of the grid was very extensive but unfortunately the interpretation was not very rigorous. After relogging the core Boyd makes the ambitious statement "These holes have thoroughly tested the possible geological, geophysical and geochemical targets identified by the first exploration work done at Beatrice" (Boyd, 1994).

Boyd stated that "the sulfide exposed in the core is bedded within the black shale and volcaniclastic units and as such is most likely to be syn-sedimentary, thus indicating that some form of seafloor sulfide deposit has occurred at this stratigraphic level". The stratigraphic position hosting the mineralisation was shown to extend 300m to the south and a drill hole was proposed to test this position. This hole was not drilled until 1996 (see below).

Boyd (1994) did a statistical and lithological appraisal of mineralisation in rock chips and concludes that the majority of the mineralisation is within the black shales. An average of 1.62% Zn, 1.79% Pb, 620 ppm Cu and 45 ppm Ag is calculated for black shale, an average of 2.52% Zn, 0.11% Pb, 365 ppm Cu and 4 ppm Ag is calculated for bedded vitric tuff and an average of 0.34% Zn, 0.22% Pb, 65 ppm Cu and 3.7 ppm Ag is calculated for the rest. Samples were collected for sulfur isotope analysis from the drill hole MS1. $\delta^{34}S$ values for galena, sphalerite and pyrite are +15.8 - +14.9 ‰. These values are similar to the isotopic values for sulfur from the top of the Rosebery deposit ($\delta^{34}S$ +13.2 - +15.6 ‰). No lead isotope data has been collected at the prospect.

1996: In 1996 minor mapping and one diamond drillhole (MS6; 288.8m) were completed (Joyce, et.al 1997). DDH MS6 was drilled to test the black shale horizon 500m to the south of existing drilling and adjacent the Comstock Valley Fault (approximately 500m north of this structure) which was interpreted as a synvolcanic shear. No significant mineralisation was intersected, with a best assay of 2.6m @ 0.25% Zn. RGC Exploration relinquished the area in October 1997 and it was successfully tendered for by Pasminco Exploration.

5.2 West Sedgwick Prospect

The West Sedgwick area covers the western and southwestern flanks of Sedgwick Bluff (not Mt Sedgwick itself). The first exploration in the area was in 1957 when Rio Tinto Australian Exploration (RTAE) completed a TEM survey. Since this time the area has been explored by Mount Lyell Mining and Railway Company (MLMRC), Pickand Mathers and Co. International (PMI), Goldfields Exploration, BHP and RGC Exploration.

The majority of previous work has concentrated at the top of the Central Volcanic Complex around the southern end of Sedgwick Bluff, in the vicinity of Zig Zag Hill, where there are several east-west cross structures. This stratigraphy probably continues to the north but exploration efforts have been hampered by scree and glacial moraine cover.

Rio Tinto

Rio Tinto Australian Exploration (Muceniekas, 1958) completed a EM survey and a 600m long weak anomaly centre at roughly 46900 mN, 81800 mE was identified (Zig Zag Hill anomaly). To follow up the anomaly detailed geological mapping, stream and soil geochemistry, ground magnetics and a gravity survey were completed. Minor outcrop revealed that the alteration was similar, but weaker, to the Mt Lyell field. A weak Pb in soil anomaly coincides with the EM anomaly. No further work was done until 1962 when RTAE (in joint venture with EZ Co) completed a three electrode array IP survey along 6 grid lines. There was no IP response associated with the EM anomaly and no further work was completed.

Pickand Mather and Co International (PMI)

PMI pegged the ground in 1965 as part of EL 12/65. They completed reconnaissance geology, stream sediment geochemistry and by 1967 their exploration efforts had focussed on the volcanic-conglomerate contact. A dipole-dipole survey was completed and an anomaly was identified close to the Zig Zag Hill anomaly, but, PMI concentrated their efforts on a larger anomaly located at Basin Lake (outside the current tenement). No further work was done on the area until MLMRC pegged the ground in 1971.

Mount Lyell Mining and Railway Company (MLMRC)

MLMRC held this round under EL 41/71. In their first report they make the comment *"Pickand Mathers exploration philosophy appears to have been based on the often stated, but invalid, premise that the Lyell orebodies are related genetically to the volcanic-conglomerate contact"*. Their exploration focussed to the west mainly within the Yolande River Sequence. An extensive grid (East-west lines on 070° and spaced at 600'), was cut and was labelled with the MLMRC trademark Northing and Southing. From 1971-1973 exploration concentrated on

mapping (Sheppard, 1972 and 1974), much of which was grid based, and the presence of the Tyndall Group (Dora Conglomerate) was first recognised. In 1973 the Lake Margaret Tram Pyrite Lens, a 10 foot wide zone of pyrite (30%) and quartz (70%) containing up to 1g/t Au, Ag to 1 g/t, Cu to 1020 ppm and very low Pb and Zn, was discovered. In the same year an IP survey was completed by Scintrex; a total of 38 anomalies were defined of which four were regarded as significant (Sheppard, 1975).

During 1974 (Sheppard, 1975) the grid was extended and soil samples were collected over the 38 anomalies at 50' centres and at 25' centres over the four major anomalies. In 1975 (Brophy and Stevens-Hoare, 1976) and 1976 (Meares, 1977) some additional grid extensions were cut and a blanket gradient array IP survey and a smaller pole-dipole survey were completed. These surveys located a 150' wide, 2000' long black shale horizon on the east flanks of Crown Hill. The Lake Margaret Tramway pyrite lens had no IP response.

During 1977 three diamond drill holes were drilled to test the Lake Margaret Tramway pyrite lens and a combined IP/geochemical anomaly on line 84S (Meares, 1978). This drilling was completed during June-September 1977 and was reported in an Appendix to the 1977 report (Meares, 1977).

DDH WS1 and WS2 tested the Lake Margaret tramway pyrite body and were collared at approximately 5345500 mN, 379200m. Hole WS1 was abandoned at 92 metres due to drilling problems. Six samples of the black shale and 36 samples of the tuff from hole WS2 (224.4m) were assayed for Cu, Pb, Zn; All results were very low. DDH WS3 (259.7m) was targeted at an area combined chargeability and Pb in soil anomaly within black shales. It was collared at approximately 5346400 mN, 380200m. Five samples were collected of the black shale unit and 12 samples of the volcanics. The black shale was anomalous in Pb (range 420-760, average 572 ppm) and Zn (range 185-1100, average 512 ppm).

In 1980-81 Mt Lyell cut an extensive grid over the Comstock Valley and completed an IP survey. Some of these lines extended across the CVC-Owen Conglomerate contact north of Zig Zag Hill. No significant chargeability anomalies were identified in the West Sedgwick area.

The review of EL 9/66 (Purvis et al., 1983) highlighted the area of the old RTAE EM anomaly as being prospective. No action was taken on this recommendation until 1985 (FitzGerald and Cartwright, 1986) when anomaly was followed-up with three lines of SIROTEM. A weak WNW anomaly parallel to the RTAE anomaly was identified and was interpreted to be a weakly conductive zone. This anomaly occurred in an area of Owen Conglomerate scree and it was tested by the drilling of WS4 (229.8m) which failed to intersect any significant mineralisation (Fitzgerald, 1987).

BHP

The tenement was relinquished by Goldfields and pegged as EL 102/87 by BHP (Kerr and Wilde, 1989). They relocated all the previous grid data and quite unbelievably there are four grids in the West Sedgwick area and even more unbelievably they are all at different orientations (see Figure 2 from Kerr and Wilde 1989). These are the West Sedgwick grid, North Queen Grid, Mine lease AMG grid and the Comstock AMG grid.

The BHP approach was to cover areas with blanket UTEM. They cut an additional 106.7 kilometres of lines and fortunately they did not choose a fifth grid orientation. A UTEM survey was completed by Lamontagne Geophysics, and results are reported in Kerr and Wilde (1990). An early time feature in these data corresponds to the GLF. Another well defined early time anomaly extends NW from 5346000 mN, 380700 mE, to 5346800 mN, 380225 mE. This feature corresponds with the anomalous Pb/Zn soils tested by WS3. No other major anomalies were identified.

BHP also revisited the Tramway pyrite zone. The zone was described by Sheppard (1972) as a pyrite outcrop but is a pyritic quartz sericite schist. The zone is two metres wide and probably <30m strike length. Rock chips return up to 0.76 g/t Au. The drillhole that tests this zone, WS2 was not analysed for Au. MLMRC only collected six samples from the shale in WS2 and had a best result of 1.5m @ 93 ppm Cu 420 ppm Pb. BHP cut some additional samples from the shale and report a best assay of 1.4% combined Pb/Zn. BHP joint ventured EL 102/87 with RGC Exploration in November 1991.

RGC Exploration

RGC Exploration's exploration strategy was to use mapping and geochemistry, in contrast to BHP Exploration's blanket UTEM. Their work concentrated on the SW corner of Mt Sedgwick. During 1991/92 the West Sedgwick area was mapped at 1:5000 scale, 139 rock chip samples were collected and C-horizon soil samples were collected (Halley, 1992).

During 1992/93 the core from WS4 was re-logged. It was recognised that the hole did not go through the andesite (that occurs at the top of the CVC) and the grey carbonate that was intersected from 209.1m - 210.8m was interpreted as a low temperature exhalite (Halley, 1993). WS5 was then drilled to test the volcanics near the intersection of the West Sedgwick and Great Lyell Faults. It was originally planned to lengthen WS4 however the PVC could not be removed from the hole and a new hole was collared. WS5 was abandoned at 97.9m due to the rod string

breaking and WS5A was lipped of WS5 at 52m. WS5A intersected a major fault at 124m in which the hole was abandoned.

WS6 was completed at 380.8m and intersected a sequence of coarse grained hornblende-phyric andesites to 219.6m with major faults at 121.9-123.4 and 212.6-219.6m. Beyond the second fault the Tyndall Group was intersected and was represented by a sequence of interbedded siltstones and felsic epiclastics followed by the Comstock Tuff. The Great Lyell fault was intersected at 373.0m. Core was analysed for Au, Ag, Cu Pb and Zn, but, there were no significant assay results.

During 1993-94 a series of 400m spaced holes were drilled to test the CVC-Tyndall Group contact close to the GLF. Two holes were drilled from the Mt Lyell Mine lease and WS7 was drilled from the saddle between Agglomerate Hill and Zig Zag Hill. WS7 (499.2m) intersected the CVC-Tyndall Group contact but this was unmineralised. Zones of silica-sericite-pyrite alteration were intersected from 45 to 155m and from 295 to 350m. Ninety three samples were submitted for assay (including 36, 10m core grind composite samples and 57, 1m intervals of ½ core). Assay results were disappointing with no base metals above 1000 ppm (Halley 1994). Two samples from WS7 were submitted for whole rock ^{18}O analysis and three pyrite samples from the alteration zones were submitted for $\delta\ ^{34}S$ analysis. The whole rock ^{18}O results indicated that the alteration was formed by fluids at around 200^{0}C, which is to cool to carry significant base metals. The $\delta\ ^{34}S$ results indicated that the sulfides were formed from sulfate reduction and that the alteration is on the edge of a large system (the Mt Lyell system?). The only other recorded highly enriched ^{34}S and high ^{18}O from the MRV is in the stringer envelope zone at Hellyer (Halley, 1994).

Downhole SIROTEM was completed in WS6 and WS7 and Crone 3-component pulse EM was read in WS7; No offhole conductors were identified.

During 1994-95 hole WS8 was drilled from the same site as WS7 and was designed to test the bedded pyrite unit and pyrite alteration zone intersected in hole WS7 at 200m down dip (Halley et.al 1995). This hole was drilled to 652.1m, but, failed to intersect the sulfides seen in WS7. WS8 also failed to intersect the Tyndall Group; this was explained by RGC with an oddly located flat fault, however, on relogging the hole it is apparent that much of WS8 was drilled down bedding. No further work was completed at West Sedgwick.

5.3 Walford Peak

For a comprehensive review of previous exploration in the Walford Peak area the reader is referred to Weber, Murphy and Aliano (1997). Recent exploration has focussed on the Dora Prospect and previous work over this area is summarised below.

Dora Prospect

Considerable prospecting was done in the Dora-Spicer area in 1896-1899, during the Copper boom, with the establishment of many small workings. None of these yielded either the hoped for grades and tonnages and the field was abandoned by 1909 (Harcourt Smith, 1898; Blake and Henderson, 1939).

Modern exploration began around the old copper workings in the area in 1969. Mt Lyell Mining and its successor Goldfields, held the area as part of EL 9/66. As part of a regional exploration effort, the volcanic belt stretching from Lake Dora to the Selina area was gridded, mapped, soil and rock chip sampled (Newnham, 1970; Meares et al., 1982). Geophysical surveys included pole-dipole IP, SP, fluxgate magnetics and EM. In 1983, following a data review, Gold Fields collected some dump samples (Purvis et al., 1983) and in 1985 they relinquished the area.

CRAE took up the area as part of EL 5/85. Attracted by the Goldfields best dump assay of 2.0g/t Au, CRAE conducted a stream sediment, rock chip and dump sampling programme aimed at ascertaining the gold potential of the area (Funnell, 1987). Gold assays from dump sampling were in the 0.1g/t range, with a best 0.37g/t Au. CRAE also conducted a UTEM survey to search for massive sulphides which might not have been apparent in the IP results due to the highly variable chargeability response of the area (Funnell, 1987).

Aberfoyle took over management of EL 5/85 in 1988. Their work comprised field checking of earlier mapping, some further petrology and dump sampling, which returned a best result of 0.15g/t Au with 0.42% Cu (Lewis, 1994).

It should be noted that the southern part of the Dora Prospect was not part of this modern exploration effort. The Goldfields grid only extended south to the northern part of Lake Dora, and their maps indicate the southernmost part of the old mineral field was held under mining lease at the time of their exploration. Similarly, EL 5/85 only extended south as far as AMG 5354000N. Old workings extend for 1km to the south from 5354000N, and most of the interesting aeromagnetic and gravity anomalies lie in this southernmost area.

6. WORK COMPLETED

6.1 Beatrice Prospect

The majority of effort was at the Beatrice Prospect where the following work was completed:

- Detailed 1:1000 scale mapping.
- Compilation of previous mapping.
- Relogging of the six old holes (MS1-MS6).
- A 580 sample MMI soil sampling programme.
- A 4 line 8.8 km pole-dipole induced polarisation survey.
- An orientation 2 line 4.0 km CSAMT survey.
- 4 diamond drill holes for 2392.6m.
- Downhole EM on the four drill holes.

6.1.1 Geology

The main tracks in the Itat Creek area were mapped at 1:1000 scale (Plan 1) and the previous mapping for the area was compiled and interpreted (Plan 2). To further assist with the geological interpretation of the prospect the 6 holes (MS1-MS6) were relogged. MS1-MS5 were located at the MRT coreshed at Mornington and MS6 is stored at the Pasminco Coreshed at Tullah. These drill logs are included as Appendix 1 and sections are given as plans 3-5.

As a result of this work, and results from the drilling of MS7-MS10 (see below), a simple (simplified) stratigraphy was recognised. In the Itat Creek area (Plan 1) the stratigraphy, from west to east, is basal feldspar phyric lavas and volcaniclastics (lava breccias) interpreted to be Central Volcanic Complex (CVC) equivalents, progressively overlain by fine volcaniclastic siltstones (ash volcaniclastics) with minor shale, coarse graded mass flows and black shale with quartz-feldspar porphyry sills. The Itat Creek sequence, above the CVC, are interpreted to be Tyndall Group correlates.

In the Itat Creek area the volcaniclastic and sedimentary units strike NW and in general dip and face to the SW. In the vicinity of MS3 there is some overturning with bedding dipping to the NE. To the west of this volcaniclastic and sedimentary sequence a major quartz-feldspar porphyry body is exposed. Drilling has confirmed that the porphyry is a series of sub volcanic sills that intruded into wet sediment with peperite commonly developed at the top and base of each sill. The porphyry body has a faulted contact with the volcaniclastic and sedimentary sequence in the Itat Creek area (Itat Creek fault). The Itat Creek Fault is a NS striking, east dipping, crush and fracture zone with minor pug, best developed in DDH MS6.

The IP survey completed by MLMRC in 1977 (Walter, 1977) shows the zones of highest chargeability occur over the porphyry. This was drill tested by MLMRC in 1979 and black shale was intersected at a shallow depth. The shale was interpreted to explain the high chargeability and the hole was terminated. The presence of the black shale underneath the porphyry and the stratigraphic sequence recognised in the Itat Creek area suggested the potential for the Itat Creek stratigraphy to be repeated beneath the porphyry. This interpretation, also suggested by previous workers, significantly increases the exploration potential at the Beatrice Prospect.

On the ridge immediately east of Itat Creek a quartz-feldspar porphyry is exposed and has a similar IP response to the western quartz-feldspar porphyry body. Field checking has confirmed the presence of black shale as float. It is interpreted that the Itat Creek stratigraphy is repeated on this ridge and this implies either rapid thinning of the sequence or the presence of an additional Itat Creek parallel fault (Plan 2).

The base metal mineralisation at Beatrice occurs as disseminations, veinlets, clots and clasts (clast replacements) mainly within the black shale, coarse volcaniclastic and fine volcaniclastic but also within the quartz feldspar porphyry. Occasionally the veinlet density is high and a sphalerite stockwork is formed (eg MS10 459.2-460m and 620.7-622.5m).

6.1.2 Geochemistry

Rock chip sampling on the main tracks within Itat Creek (location and assay data in Appendix 2) identified 10-20m wide intervals of Pb/Zn mineralisation, with several modal% fresh sulphides in places, associated with epiclastic sediments beneath black shales. Almost all the rock chip samples collected have elevated Au, Pb, and Zn. The best results come from two hand picked samples which assayed, 10.51% Zn, 2.1% Pb, 2.4 g/t Au and 16.1 g/t Ag, and 4.6% Zn, 1.96% Pb, 0.70 g/t Au and 11.1 g/t Ag respectively. The best rock chip assayed 2.4% Zn, 1.9% Pb, 0.37 g/t Au and 9.3 g/t Ag over 2m. These samples also have elevated Ba, Cd, Mn, Mo and Te. Interestingly copper is very low in these samples with a highest result of 464 ppm. Petrographic descriptions of nine of the mineralised rock-chip samples are also included in Appendix 2.

Two distinct chemical signatures associated with basemetal mineralisation are noted from multi-element analysis of the core assays. The strip log from DDH MS8 (Figure 4) demonstrates this well. From 560-580m zinc and lead mineralisation has associated Mn, Ag, Cd, Co, Fe, Sb and possibly Ni and Sn. This is the most common mineralisation type of sphalerite in blebs, disseminations and associated with carbonate veinlets. Zinc and lead mineralisation intersected from

770-780m has no elevated Mn and has associated Ag, Cd, Co, Fe, Sb as above but also elevated As, Au and Bi. This mineralisation is associated with a late-stage quartz-carbonate- arsenopyrite-sphalerite veinlet and the element assemblage is considered to be indicative of some magmatic input.

A 685 sample (including standards and duplicates) mobile metal ion (MMI) survey was completed over the entire Beatrice grid which was refurbished as part of this exercise. Samples were collected over the entire grid with samples collected at 25m intervals and composited at 50m intervals (with the exception of SDS 3724 that was sampled on 25m centres). Samples were submitted to Amdel for analysis of Cu, Pb, Zn, Ag, Au, Ba, As, Cd, Co, Bi, Mo, Ni, Pt, Pd, Sb, and Tl by proprietary method DL40. Results are included in Appendix 3 and sample locations are shown on Plan 8.

The samples were analysed in four batches and there were significant levelling problems between the batches; the principal component analysis outlined below partially removes this effect, but, interpretation of individual elements was done using datasets levelled to the median for each batch.

Principal component analysis was completed for all elements, with the exception of Au, Tl, Pt and Pd for which a large proportion (>50%) of the data have below detection limit results. Three elemental factors were defined by this analysis (Figs. 4, 5 and 6). One of these factors (Factor 1: As, Bi, Sb, Pb and Ba, Fig. 4) is regarded as a proximal indicator to mineralisation. The main mineralised zone at Itat Creek is highlighted by this factor (as would be expected for a proximal indicator). Factor 2 (Co and Ni; Fig. 5) appears to define the outline of the Jurassic Dolerite and an anomaly train down the course of Itat Creek resulting from the presence of dolerite boulders in the thin glacial deposits in the valley. This factor is therefore interpreted to reflect lithological variations rather than indicate the presence of buried mineralisation. The third factor (Factor 3: Ag, Cd, Cu and Zn, Fig. 6) is regarded as a distal indicator of mineralisation. Factor 3 may be particularly useful for highlighting target areas beneath the quartz porphyry and two such areas can be seen on Figure 6. The first is the northern end of the Itat Creek area where there is coincidence of two of the factors. This is a very clearly defined anomaly that is also obvious in the levelled Zn data (Figure 8). Holes MS7, MS8 and MS10 were drilled to test this anomaly.

The second area is in the western part of the grid, highlighted in Factor 3. Subsequent field inspection of this anomaly has shown it to be associated with weak sericite-K-feldspar alteration of the quartz-feldspar porphyry. This is an extensive anomaly (at least 500m long; Fig. 8) which is also associated with a resistivity low in the 1979 MLMRC IP data.

The third area is in the southeast portion of the grid, in an area of glacial cover with some outcropping Owen Conglomerate to the west. The anomaly is not closed-off and further sampling on the adjacent EL 13/99 Linda is required to detail the anomaly prior to further follow-up.

6.1.3 Drilling

Four diamond drill holes (MS7-MS10) were completed for 2392.6m. All of the holes were drilled by Diamond Drilling Tasmania using a CS1000 P4 rig. The rig was dragged into the MS7 site using an excavator and was positioned at the remaining sites using a Squirrel Helicopter from Helicopter Resources.

A summary drill log was completed at site and the drill core was then flown and then driven from the drill site to Pasminco's core farm at Tullah. The core was measured (for recoveries), photographed, geologically logged and magnetic susceptibility measurements were made (readings taken at each core block, or in some cases on 1m intervals). Drill core was cut and samples analysed by Analabs for Ag, As, Bi, Ca, Cd, Cu, Co, Fe, K, Mg, Mn, Na, Ni, Pb, Sb, Sn and Zn using ICPMS, Au by 50g fire assay and Ba by pressed powder XRF.

Drill sections are presented as plans 3-5, drill logs, down hole surveys and collar details are included in Appendix 1, assay results in Appendix 4 and magnetic susceptibility measurements are presented in Appendix 5.

<u>MS7</u>

This hole was designed with two aims in mind:

1. To test the interpretation that the Itat Creek stratigraphy occurs underneath the quartz feldspar porphyry and to test for mineralisation within this stratigraphy.
2. To test the geology on the eastern side of the Itat Creek Shear at depth.

Hole MS7 was commenced on the 23/11/98 and completed on the 21/1/99 at a depth of 550m. A summary log of the hole is shown as follows:

From	To	
0.0	109.3	Quartz feldspar porphyry.
109.3	231.8	Black shale
231.8	254.0	Quartz feldspar porphyry with pepperitic top and base
254.0	261.2	Black shale
261.2	417.3	Coarse pumiceous volcaniclastic massflows.
417.3	550.0	Ashy volcanic, minor massflow units

This hole confirmed that the mineralised stratigraphy, black shale underlain by coarse volcaniclastic and then fine ashy volcaniclastic, seen in Itat Creek is repeated beneath the quartz-feldspar-porphyry west of the Itat Creek shear. This result has major implications for the prospectivity of the Beatrice Prospect as there is now known potential to host mineralisation beneath the quartz-feldspar-porphyry. Core orientations indicate that stratigraphy has an overall N-NE strike and a steep (60-80°) westerly dip, although folding complications may be present (Plan 3). The hole failed to penetrate the Itat Creek Fault, and it is probable that the fault is shallower than interpreted, although this may be by as little as 2-3°.

MS7 failed to intersect ore-grade and(or) width mineralisation, however, broad intervals of low grade mineralisation are indicated from assay results. Significant intersections, calculated on the basis of Zn content, were:

at a 0.1% Zn cut-off:
109.3-113.0m, 3.7m @ 0.24% Zn, 0.05% Pb, 45 ppm Cu and 1.3 g/t Ag.
132.0-134.0m, 2.0m @ 0.19% Zn, 0.04% Pb, 49 ppm Cu and 0.9 g/t Ag.
180.0-198.0m, 18m @ 0.18% Zn, 0.11% Pb, 75 ppm Cu and 1.7 g/t Ag.
254.0-255.8m, 1.8m @ 0.22% Zn, 0.03% Pb, 44 ppm Cu and 0.4 g/t Ag.
261.2-265.0m, 3.8m @ 0.14% Zn, 0.07% Pb, 59 ppm Cu and 1.2 g/t Ag.
285.0-307.0m, 22.0m @ 0.2% Zn, 0.07% Pb, 70 ppm Cu and 1.5 g/t Ag.
315.1- 325.0m, 9.1m @ 0.16% Zn, 0.11% Pb, 58 ppm Cu and 4.6 g/t Ag.
364.0-366.0m: 2.0m @ 0.14% Zn, 0.18% Pb, 53 ppm Cu, and 0.8 g/t Ag.
374.0 -378.0m, 4.0m @ 0.17% Zn, 0.35% Pb, 189 ppm Cu, 1.3 g/t Ag.
394.0-405.0m, 11.0m @ 0.15% Pb, 0.07% Zn and 1.2 g/t Ag.

As values peak at 236 ppm in the mineralised interval between 285 and 325m, but, decrease significantly downhole (to generally <10 ppm). Au values are uniformly low (97% of assays are <0.01 ppm), with a maximum of 0.6 g/t at 388-390m (this elevated value is not associated with elevated base metals, Ag or As). Cu contents are also low (<70 ppm) with the exception of two spikes of 520-550 ppm Cu at 474-476m and 499-501m where minor chalcopyrite in veins, associated with chlorite-K-feldspar-hematite alteration was intersected.

Much of the base metal mineralisation in the black shale units is not visible and must be finely disseminated and(or) mixed with the visible pyrite, however, from 184-196m a zone of thin (<5 mm) carbonate veinlets with disseminated sphalerite and minor galena was intersected. Minor disseminated and veinlet sphalerite appears to be associated with chlorite altered volcaniclastic from 374-377m, and 401.1- 407.7m and sphalerite+galena replacement of carbonate-rich clasts and nodules, in coarse volcaniclastics, was recorded at 317.0-320.0m and 390.9 – 407.4m.

Magnetic susceptibilities were measured at the core block markers for the entire hole (Appendix 5). Zones of K-feldspar+magnetite±chlorite alteration in the quartz-feldspar-porphyry (28-88.5m) and in the ashy volcaniclastic (491-499m) are confirmed by high magnetic susceptibility readings.

Downhole EM was also completed on the hole. Off-hole anomalies were recorded and are interpreted to reflect variably conductive shale units rather than massive sulphide accumulations. The reader is referred to Appendix 8 for additional information.

MS8

This hole was designed to test a very clearly defined MMI anomaly that is located on quartz feldspar porphyry (see section 6.1.2) in the northern part of the Beatrice Grid. Hole MS8 was collared on 22/1/99 and completed on 7/5/99 at a depth of 798.7m. A summary log of the hole is as follows:

From	To	
0.0	191.8	Quartz feldspar porphyry.
191.8	197.8	Volcaniclastic sandstone and shale.
197.8	292.9	Quartz feldspar porphyry.
292.9	306.2	Intercalated black shale and quartz feldspar porphyry
306.2	318.2	Black shale
318.2	344.2	Intercalated black shale and quartz feldspar porphyry (pepperitic contacts)
344.2	373.7	Black shale and minor sandstone; major fault zones at 360.1-364m and 371.6-373.7m; Sphalerite-rich mineralisation in lower 2m of unit.
373.7	447.3	Quartz feldspar porphyry. Strongly Sil- Co- Chl ± Kfs veined with weak sphalerite>galena mineralisation.
447.3	583.3	Black shale and minor siltstone/sandstone. Sphalerite> galena Mineralisation from 557 - 583.3m.
583.3	651.6	Quartz-feldspar-porphyry
651.6	665.4	Ash volcaniclastic and minor volcaniclastic sandstone. Generally 0.5-1.0% sphalerite, but, up to 5% sphalerite in matrix of sandstone units.
665.4	696.5	Volcaniclastic sandstones (pumiceous) with trace sphalerite.
696.5	787.3	Intercalated shale and volcaniclastic ash to sandstone units. Variable Py±Sp>Gn mineralisation; narrow intervals of up to 10% Sp (in sandstone beds) but generally <0.5% Sp.
787.3	798.7	Lava breccia with Sil+Kfs/hem/mag alteration. Only trace Py+Cpy (CVC correlate)

The stratigraphy in this hole was largely as predicted, with the exception of the presence of quartz-feldspar porphyry intruding lower into the sequence than seen in other holes and the presence of more individual sills of porphyry. The presence of significant mineralisation in the "ash volcaniclastic" (although often more common in fine sandstone beds rather than the ashes themselves) is consistent with results from drilling in Itat Creek (e.g., MS3), however, there appears to be a larger shale component in the "ash volcaniclastic" unit in this hole than previously intersected. Mineralisation (veins, disseminations and some clast replacement) occurs in the shales, coarse volcaniclastics and ash volcaniclastics, but, is rare in the porphyry sills, with the exception of the unit from 373.7 – 447.3m where minor sphalerite, galena and arsenopyrite occur in late carbonate-chlorite-silica veins. The lower part of the black shale in DDH MS8 hosts grey carbonate-rich nodules (also seen in MS7) and thin beds of calcareous mudstone; these are strongly replaced by sulfides (pyrrhotite+chalcopyrite+sphalerite+galena) from 561.9-568.1m. The carbonate-rich beds and associated mineralisation were not seen in previous drilling (largely east of the Itat Creek Fault). Core orientations give consistent bedding orientations, shallowly east dipping, in the interval 494-529m and steep north dipping in the interval 722-740m. The hole was finally terminated when CVC like lave breccias with 'granite' type alteration were intersected.

Assays from the hole are included in Appendix 4. Intersections from the hole are:

at a 0.1% Zn cut-off:

242.7 - 250.4m, 6.7m @ 0.24% Zn, 0.21% Pb and 2.5 g/t Ag
316.0 - 318.0m, 2.0m @ 0.25% Zn, 275 ppm Pb and 1.2 g/t Ag within black shale.
337.4 - 340.6m, 3.2m @ 0.17% Zn, 512 ppm Pb and 1.3 g/t Ag within shale and porphyry.
344.2 - 352.2m, 8.0m @ 0.16% Zn, 625 ppm Pb and 1.4 g/t Ag within black shale.
359.6 - 363.7, 4.1m @ 0.33% Zn, 0.14% Pb and 2.3 g/t Ag within black shale.
410.0 - 412.0m, 2.0m @ 0.11% Zn, 0.3% Pb and 5.3 g/t Ag within porphyry.
434.0 - 436.0m, 2.0m @ 0.16% Zn, 53 ppm Pb and 0.2 g/t Ag within porphyry
446.4- 457.0m, 10.6m @ 0.19% Zn, 500 ppm Pb and 2.1 g/t Ag within black shale
462.6 - 474.0m, 11.4m @ 0.12% Zn, 630 ppm Pb and 1.1 g/t Ag within black shale
515.0 - 583.4m, 68.4m @ 0.49% Zn, 0.21% Pb and 7.8 g/t Ag within black shale
590.1 - 591.8m, 1.7m @ 0.49% Zn, 580 ppm Pb and 0.6 g/t Ag within porphyry
651.6 - 666.4m, 14.8m @ 0.34% Zn, 0.13% Pb and 3.5 g/t Ag within ashy volcaniclastic
684.3 - 702.9m, 18.6m @ 0.22% Zn, 780 ppm Pb and 1.6 g/t Ag in volcaniclastic sandstone.
707.6 - 754.1m, 46.5m @ 0.29% Zn, 800 ppm Pb and 2.6 g/t Ag in shale and ashy volcanic.
758.3 - 784.4m, 26.1m @ 0.37% Zn, 0.12% Pb and 5.1 g/t Ag in shale and ashy volcanic.

at a 1.0% Zn cut-off:
561.9m - 562.9m, 1.0m @ 1.58% Zn, 0.71% Pb and 26.7 g/t Ag
567.0m - 569.0m, 2.0m @ 1.18% Zn, 0.38% Pb and 14 g/t Ag
572.5m - 573.8m, 1.3m @ 1.16% Zn, 0.32% Pb and 10.6 g/t Ag
576.8m - 583.4m, 6.6m @ 1.18% Zn, 0.55% Pb and 12.5 g/t Ag
653.2m- 654.3m, 1.1m @ 1.2% Zn, 0.4% Pb and 6.9 g/t Ag
735.2m - 736.5m, 1.3m @ 1.4% Zn, 0.28% Pb and 5.5 g/t Ag
779.7m - 780.3m, 0.6m @ 1.38% Zn, 0.51% Pb, 24.8 g/t Ag, 0.4 g/t Au, 1.35% As
781.7m - 782.4m, 0.7m @ 1.14% Zn, 0.16% Pb, 3.8 g/t Ag

Cu results are generally low, <100 ppm, but scattered high values occur throughout the section, with a maximum of 1.3m @ 0.1% from 665.1-666.4m. Arsenic is spikily high, up to 0.65% on the upper margin of one porphyry body and up to 1.35% in veins in the lower part of the ash volcaniclastic unit. Au is weakly elevated throughout the assayed section (i.e., many more above detection limit assays than for MS7). Also possibly significant is the interval 648.2-651.6m, 3.4m @ 0.57% Ba, generally barium contents are <0.4%. As with DDH MS7 base metal values are uniformly low in the chlorite-feldspar ±magnetite/hematite altered volcanics (from 788.5 - 798.7m) which have <100 ppm Pb and Zn and <50 ppm Cu.

Magnetic susceptibility measurements (Appendix 5) are high in the pyrrhotite mineralised, carbonate-rich interval in the shale (561.9-568.1m) and also where "granitic" alteration is obvious in the CVC at the end of the hole (787.3m – EOH).

Downhole EM was also completed on the hole. Off-hole anomalies were recorded and interpreted to reflect variably conductive shale units and no anomalies attributable to massive sulphide accumulations were recorded. The reader is referred to Appendix 9 for additional information.

MS9

MS9 was drilled from the same site as MS8 and was targeted at the prospective Itat Creek stratigraphy beneath the quartz feldspar porphyry where IP and CSAMT features occur in the core of an anticlinal structure (see Section 6.1.4). Target depth was 250-300m with the hole planned to 420m. Hole MS 9 was commenced on 10/5/99 and completed at 387.5m on 17/6/99. A summary log for this hole is shown on the following page.

From	To	
0.0	38	Quartz-feldspar-porphyry;
38	73.5m	Quartz-feldspar-porphyry breccia with a matrix of black shale; peperite.
73.5	238.2	Black-grey shale with thin volcaniclastic interbeds. Variable disseminated pyrite; no significant visible sphalerite or galena.
238.2	387.5	Quartz-feldspar-porphyry, strongly K-feldspar/magnetite altered from 300m.

No significant mineralisation was intersected in the 'target position' (250-300m) and the CSAMT and IP anomalies were initially ascribed to the shale unit. It is important to recognise that the low resistivity anomaly is at a shallower level than the high chargeability anomaly. Basic resistivity measurements were collected from MS9 using a multimeter with the electrodes at a fixed spacing. These data clearly show that the lowest resistivities are within the peperite. The low resistivity is a result of carbonisation (graphite) of the included shale by the thermal effect of the porphyry. The peperite at the base of the upper porphyry is thicker in MS9 than in other holes (20-30m vs. 1-2m in most holes). The high chargeability is a response to a thick relatively flat lying black shale unit occurring at shallower levels in the hinge of an anticline (Appendix 6).

Assay results were as expected with almost all zinc assays around 100 ppm and only one sample returning > 1000 ppm Zn (1.5m @ 1930 ppm Zn from 72-73.5m). Pb results are also low (languishing around 100-200 ppm) with no assays above 1000 ppm Pb.

Magnetic susceptibility was measured at the core block markers for the entire hole (Appendix 5). The magnetic susceptibility is very low except for 299.2m - EOH where K-feldspar - magnetite alteration in the quartz-feldspar porphyry was intersected.

Downhole EM was also completed on the hole. Off-hole anomalies were recorded and interpreted to reflect variably conductive shale units and no anomalies attributable to massive sulphide accumulations were recorded. The reader is referred to Appendix 8 for additional information.

MS10

MS10 was targeted at the centre of the major partial leach soil anomaly in Itat Creek. The target horizon was the coarse volcaniclastic unit in the footwall of the Itat Creek Fault. Hole MS 10 was commenced on the 29/7/99 and completed at 656m on the 21/9/99. A summary log is as follows:

From	To	
0.0	21.2	Sheared Black Shale, peperitic contact to;
26.2	71.5	Quartz-feldspar-porphyry, faulted contact to;
71.5	256.0	Black Shale; interval 71.5-90.0 is strongly broken (Itat Creek Fault). Shale is variably pyritic.
256.0	311.2	Quartz-feldspar-porphyry, moderately sericite altered, peperitic contact to;
311.2	374.8	Black shale, variably pyritic, trace pyrrhotite and base metals.
374.8	492.4	Generally pumiceous volcaniclastic sandstone with minor Breccia units (dominantly limestone clasts) and ashy volcaniclastics. Variable clasts and disseminated base metal mineralisation, with 0.8m @ >10% base metal veining from 459.2-460m.
492.4	505.2	volcaniclastic sandstone interbedded with ash volcaniclastic, decreasing base metal content.
505.2	624.7	Ash volcaniclastic and minor shale, variably pyritic with minor pyrrhotite, generally minor base metals, but, narrow intervals (517-519m and 620.7-622.5m) with up to 3-4% vein and disseminated sphalerite.
624.7	635.0	Interbedded ash volcaniclastic and coarse volcaniclastic.
635.0	656.4	Coarse volcaniclastic (lava breccia in part), feldspar-phyric, variable Chlorite-k feldspar-magnetite alteration; minor pyrite and chalcopyrite (CVC).

The overall stratigraphy and lithologies intersected in DDH MS10 were very similar to those seen in MS8, including the presence of carbonate nodules and pyrrhotitc mineralisation in the lower part of the Black Shale. The major fault zone from 71.5–98.2m is correlated with the Itat Creek Fault, and most of the hole is therefore drilled in the footwall of this structure. Core orientations at 320-330m give bedding orientations clustering around dipping 55° to 330° (mag.) with bedding apparently swinging to a dip of 60-70° to 270° by 561m. Visible base metal mineralisation in MS10 is largely restricted to the "coarse volcaniclastic" interval and most of the sphalerite occurs within a blue grey siliceous breccia. The breccia consists of angular to subrounded clasts, to 30 mm, which include limestone, feldspar crystal-rich pumice, pale white volcanic clasts and blebs/clots

(clasts?) of sphalerite. The size of sphalerite clasts is similar to the other clast size suggesting that the sphalerite is replacing a particular clast type. The obvious first choice is replacement of the limestone clasts however many limestone clasts are totally unaltered and are surrounded by sphalerite. At 427.4m the breccia clearly crosscuts a clast implying the breccia is at least post diagenesis.

At the time of writing assay results have been returned for MS10 for the interval 398 - 483.6m. The best interval was 0.8m @ 8.75% Zn, 1.7% Pb, 105 ppm Ag from 459.3-460.1m. The entire interval assayed 95.6m @ 0.27% Zn, 620 ppm Pb and 3.7 ppm Ag. Intersections, calculated on the basis of Zn content, include:

At a 0.1% Zn cutoff:
398.0-402.0m; 4m @ 0.29% Zn, 260 ppm Pb, 1.7 ppm Ag
407.0-414.0m; 7m @ 0.19% Zn, 244 ppm Pb, 1.7 ppm Ag
416.2-424.0m; 7.8m @ 0.24% Zn, 260 ppm Pb, 4 ppm Ag
450.6-452.6m; 2m @ 0.58% Zn, 180 ppm Pb, 2.2 ppm Ag
456.0 –462.0m; 6m @ 1.4% Zn, 3790 ppm Pb, 21 ppm Ag
464.9-483.6m; 18.7m @ 0.22% Zn, 140 ppm Pb, 1 ppm Ag

Further zones of significant base metal veining occur at 620.7 - 622.5m where +5% Zn and 2% Pb is expected from assays, the results of which were not available at the time of writing.

Magnetic susceptibility was measured at the core block markers for the entire hole (Appendix 5). Elevated magnetic susceptibility is recorded from 350 - 371.4m which corresponds to an interval of pyrrhotitic black shale.

One loop of DHEM was completed in DDH MS10. The interpretation of the data suggests that a broad off-hole response is very similar to that seen in previous holes (MS7-9) and is related to the black shales. The reader is referred to Appendix 10 for further details.

6.1.4 Geophysics

During the year a pole-dipole induced polarisation survey and an orientation CSAMT survey were completed. A brief summary of each survey follows and the reader is referred to Appendices 6 and 7 for full reports.

6.1.4.1 Pole-Dipole Induced Polarisation Survey

The aim of this survey was to map the two-dimensional resistivity and chargeability character of the Beatrice Prospect stratigraphy with an outcome of defining anomalous response that could be attributed to base metals

mineralisation. Five survey lines (8.8 km) were completed at a cost of $61,600 (Appendix 6). It was planned to use 12 dipoles (n=12) for depth penetration however this was logistically virtually impossible. A compromise was reached using n=8, which was still logistically difficult and progress was extremely slow resulting in a very expensive survey.

The target was low resistivity and high chargeability zones, and/or an interpreted structurally favourable site. The inference that a low resistivity and/or high chargeability zone would be attributed to base metal sulphide mineralisation necessitates an assumption of homogeneity of the local black shale horizons and minimal pyrite, pyrrhotite and graphite content.

Three zones considered to exhibit anomalous resistivity and chargeability were defined from the inverted IP sections. Generally anomalous responses were observed over the shale outcrop. Diamond drillhole MS9 was targeted at the best low resistivity and high chargeability zone on Line 1800N and Line 2000N. No significant mineralisation was intersected (section 6.1.3).

The second IP target defined from the pole-dipole survey is well tested by MS02 and MS07 and also appears to have been explained by black shale responses. The third IP target is not a high priority geophysical target, however, it is associated with geochemical anomalism and should perhaps be drilled on that basis. The IP data supports a hypothesis for accompanying chargeable minerals (pyrite, galena, graphite, chalcopyrite) but does not provide a particularly anomalous response (much lower in amplitude than the target drilled at MS9), nor does the modelling provide a high confidence with regard to the source shape and/or depth. The IP target is poorly resolved and is described as a "blob" at a depth of (100-200m).

6.1.4.2 CSAMT Survey

Only two lines of CSAMT data were acquired with the initial aim of evaluating the technique for application at the Beatrice Prospect and Western Tasmania in general. In addition it was intended to see if an anomalous conductivity response could be detected below stratigraphy mapped with the IP survey with an aim of defining response that could be attributed to base metal mineralisation. Two survey lines (4 km) were completed at a contractor cost of $8,000.

The target was a zone of low resistivity and high chargeability. Much the same as the IP the inference that a low resistivity and/or high chargeability zone would be attributed only to base metal sulphide mineralisation necessitates an assumption of homogeneity of the local black shale horizons and minimal pyrite, pyrrhotite and graphitic content.

Numerous modelling and processing routines were trialed on the data and a report compiled outlining the advantages and disadvantages of each (Appendix 7). A comprehensive analysis made on the noise characteristics of the data with the aim of discriminating geological response from system and cultural induced response (not an easy task with CSAMT!).

No priority drill targets were delineated on the basis of the CSAMT results. Some minor response was detected in the vicinity of the IP response targeted by MS9, however, this would not have formed a CSAMT target in its own right.

Low resistivity zones generally conform to the location of known black shale horizons. The CSAMT modelling does not have the resolving power of the pole-dipole IP sections and only gave a gross picture of the electrical stratigraphy. Conceptually if a large highly conductive base metal orebody had been present then the CSAMT data may have resulted in identifiable anomalous response. The CSAMT data do not appear to provide enough detail to allow resolution of a moderately conductive sulphide system within variably conductive and extensive black shales.

CSAMT provided a much more economically viable technique than the IP and did provide additional depth information. Use of the technique is recommended where black shales are not as extensive as at Beatrice (e.g., exploring within the Tyndall Group). If delineation and definition of shale horizons on a regional scale was the geological goal then application of the technique could be economically viable.

6.1.4.3 DHEM Surveys

The aim of the downhole EM surveys was to delineate anomalous electromagnetic response that could be associated with basemetal mineralisation in the vicinity of completed drillholes. All drillholes were surveyed (Appendix 8-10).

Off-hole electromagnetic responses were detected in all drillholes. Initial modelling of results suggests that the responses are not coincident in location and that the actual source of each anomaly is dependent on the transmitter-drillhole geometry. The black shale (and possibly shale/porphyry peperite) at the Beatrice Prospect appears to be variably conductive providing a focus area for excitation of secondary electromagnetic fields in locations that are primarily dependent on the location of the surface transmitter loop. The offhole responses are all lithological and no targets were recommended for drill testing.

Continued logging of drillholes with DHEM is recommended especially now that the electromagnetic character of the black shale is beginning to be established. An anomalous response due to base metal mineralisation could quite easily be orders of magnitude greater than the shale response. In addition, the shale response is typically very broad in wavelength facilitating delineation of ore responses that may be closer to the drillhole (<100m) through a narrow wavelength response.

6.2 West Sedgwick.

The previous holes drilled at West Sedgwick (WS1-WS8) were relogged (Appendix 11). A full literature review of previous work was completed and is presented in section 5.2. There is considered to be good potential for discovery of a basemetal orebody in this area particularly underneath he glacial cover. Further work is planned (section 7.2).

6.3 Walford Peak.

Since the tenement was granted to Pasminco Exploration a full literature review and data analysis have been completed (Weber, et al., 1997). Pasminco's initial interest in the area was for intrusive related Cu-Au systems, possibly associated with magnetic and gravity highs (Weber et al., 1997), and for Au in a "Leyshon" style breccias in the Dora Conglomerate, similar to that interpreted in the Selina conglomerate to the north (Aliano, in Weber, et al., 1997). As an initial step in exploring the area, it was recommended that the area be mapped, to define alteration types and possible breccia units in the Dora Conglomerate, and that old workings be mapped and rock-chip sampled in detail to elucidate the style of mineralisation (Denwer, 1998).

6.3.1 Mapping

Access can be gained to the Lake Dora area via a vehicular track, commencing at the Anthony Road west of Newton Peak. It is about 16 km from Anthony Road to the Lake Dora Prospect, and the track passes directly through the centre of the prospect.

During 1997/98 the access track was refurbished, the old Goldfields grid was relocated and mapping and sampling commenced. However, during particularly heavy rainfall the track was washed out and the work program was delayed, whilst repairs to the track were completed. Mapping was only at an early stage, with five days spent on the ground, and results from this preliminary work were not included in the 1998 report (Denwer, 1998).

Detailed mapping and rock-chip sampling of the Lake Dora area was completed (intermittently) in January to June 1999 by AMcN and KPD. Rectified orthophotos at 1:5,000 scale were used as base maps, and as the country is relatively open, geology could be plotted directly onto the orthophotos. Mapping was completed over the area from Lake Spicer to approximately 1 km north of Lake Dora. It was initially planned to continue mapping to the Sticht Range – Walford Peak saddle, however, a change in exploration focus resulted in the planned mapping and sampling programs not being completed.

Mapping (Plan 6) has confirmed the overall stratigraphy as described by previous workers; a generally west facing sequence with the Sticht Range Beds at the base overlain by a wedge of Rhyolitic ?lavas, intrusives and volcaniclastics, which thickens to the north, and which in turn are overlain by the Dora Conglomerate (volcaniclastic conglomerate and sandstone) and the Siliciclastic Owen Conglomerate.

It has not been possible to confidently sub-divide the main volcanic package which has, however, been sub-divided into 6 lithofacies ranging from obviously coherent and flow-banded in part (type qfp; Plan 6) to obviously clastic (types v1, v2 and v4). Intruding into this package are at least seven small (<140x40m) bodies of feldspar-hornblende-phyric ?Andesite (two of these bodies were located previously; Lewis [1994]) which appear to be late stage intrusives (they are less altered than their hosts and appear to intrude the base of the Dora Conglomerate at 387870mE 5353540mN). The overlying Dora Conglomerate appears to have an extremely irregular contact with the volcanics, this is in part structurally related but, also appears to be partly a primary sedimentary feature. Our mapping indicates that the Dora Conglomerate extends further to the north, immediately west of Michael Tarn and on the slopes of Walford Peak (around 386660mE 5355680mN), than shown on previous maps and forms a probably continuous unit beneath the Owen Conglomerate. The contact between the Dora and the Owen Conglomerate appears to be conformable, and in one locality, gradational over <1m.

The major alteration type in the Dora-Spicer area is chlorite±silica. This alteration assemblage is restricted to the volcanic package between the Sticht Range Beds and the, essentially unaltered, Dora Conglomerate. In the field the strongly chlorite

altered rocks are mainly volcaniclastic lithofacies which are covered in a conspicuous orange lichen, which highlights the presence of this alteration. Previous workers have indicated a close association between the pervasive silica-chlorite alteration and magnetite/hematite veining and(or) pyrite/chalcopyrite mineralisation, and this is supported by our mapping. It has been assumed that the chloritic alteration represents an extensive alteration zone, however, when Aberfoyle sent samples to Tony Crawford at the University of Tasmania for petrology, he described the alteration as compatible with regional burial metamorphism.

Narrow restricted zones of intense silica-sericite-pyrite alteration, between zones of strong sulphide veining, and pervasive, but restricted, zones of Silica+k-feldspar/hematite are the two other main types of alteration (see Plan 6). Variable Hematite alteration occurs at the top of the Dora Conglomerate, immediately below the Owen Conglomerate, in the southern part of the area and a zone of jaspery hematite alteration of a rhyolitic ?lava margin was recorded near 387150mE 5354500mN.

Mineralisation ranges in style from disseminated pyrite ± chalcopyrite to vein chalcopyrite + magnetite (± malachite and azurite) ± sphalerite/galena and disseminated pyrite + galena + fluorite. The host chloritic alteration zone appears to narrow to the north, beneath Walford Peak, and mineralisation becomes dominated by magnetite + chalcopyrite/pyrite veins and narrow (to 0.3m width) zones of strong (30-60%) sulphide development dominated by pyrite, with lesser galena, chalcopyrite and sphalerite. Cobalt–rich minerals are known to occur in association with strong pyrite veining (see below).

6.3.2 Rock chip Geochemistry

During the reconnaissance mapping eleven samples were collected from old workings in the Lake Dora area (Appendix 12). The mineralisation in these old working occurs as pyritic and sheared volcanic within chlorite altered rocks. The samples have quite wide ranges in all elements detected. Samples have low to moderately elevated Cu (87- 7008 ppm), gold (<0.01 to 0.39 g/t Au), Pb (41-1962 ppm) and Zn (338-2074 ppm) and all have anomalous silver (2-12 ppm).

During the detailed mapping phase a further 54 rock-chip samples were collected, largely from the dumps at old workings, and were analysed at Analabs for Ag, As, Bi, Cd, Cu, Co, Fe, Mn, Ni, Pb, Sb, Sn and Zn using ICPMS, Au by 50g fire assay and Ba by XRF. Results are included in Appendix 12 and sample locations are shown on Plan 7.

The most interesting results are from old workings on the SE slopes of Walford Peak, in the central-northern part of the mapped area. three zones of interest were located:

1. A cluster of workings and outcropping vein (sulphides +/- magnetite) and breccia-matrix style mineralisation, hosted by chlorite-silica altered volcanics, in a zone approx. 50m wide with a strike length of >200m (commencing at 387030mE, 5355535mN and not closed off to north). The best result from this zone was from the southernmost working which returned 9.65% Zn, 2.1% Pb, 0.5% Cu, 0.5 g/t Au and 58 g/t Ag (331941). However, mineralisation is patchy with other dump samples from the same working returning 0.2-0.9% Zn, 0.5-0.9% Pb, 0.3-0.5% Cu, 0.1-0.4 g/t Au and 54-88 g/t Ag. Other significant results from this trend include:

   Sample 331938 (dump sample from a >10m deep shaft) 1.74% Zn, 0.85% Pb, 3.25% Cu, 1.1 g/t Au and 48 g/t Ag.

   Sample 331933 (outcropping pyritic veining) 1.9 g/t Au, 16 g/t Ag, 0.2% Cu, 110 ppm Zn and 430 ppm Pb.

2. A single small pit on a ridge of strongly chlorite-silica altered quartz-eye volcanics at 386845mE, 5355385mN. Sulphide-rich vein mineralisation from this pit returned (331931) 48.8 g/t Au, 250 g/t Ag, 3.85% Cu, 0.1% Zn, 0.46% Pb, 6.2% As and 2.25% Co (the high As and Co resulting from the presence of erythrite (a CoAs oxide) first noted by Harcourt Smith [1898]). The host rocks to these veins (with disseminated sulphides) returned 0.3 g/t Au, 4 g/t Ag, 0.1% Cu, 0.2% Zn and 0.14% Pb. Sampling of an adit at the foot of this ridge did not return significantly anomalous results, apart for 0.2% Zn (sample 331960). However, previous sampling of this adit returned significantly higher results (6.3% Cu, 2 g/t Au, 0.5% Pb, 0.4% Zn and 152 g/t Ag; sample 1167 from Purvis et al., 1983).

3. A 25m long trench with up to 0.3m wide zones of sulphide-rich mineralisation at 386735mE, 5355215mN. The mineralisation returned 0.04 g/t Au, 14 g/t Ag, 1.1% Pb, 1.2% Zn and 0.14% Cu (Sample 331927), whilst mineralised host returned 0.19 g/t Au, 63 g/t Ag, 0.37% Pb, 1.2% Zn and 0.3% Cu (Sample 331928). This trench occurs at the northern end of a 150m long zone of magnetite (±sulphide) veined and chlorite altered volcanics (best assay; 0.3 g/t Au, 19 g/t Ag, 0.32% Pb, 0.4% Zn and 0.04% Cu). Previous sampling by RGC (Purvis et al., 1983) from a trench at the southern end of this trend (not re-located in the current survey) returned 0.5% Cu, 2.3% Pb, 5.5% Zn, 0.8 g/t Au and 115 g/t Ag.

Elsewhere in the mapped area strongly anomalous base metals (Pb-Zn) are restricted to dump samples from the Lake Dora Mine (magnetite±sulphide veining at 387965mE, 5353555mN) and samples from a pit above this adit (best sample; 0.14 g/t Au, 89 g/t Ag, 1.8% Pb, 4% Zn and 0.18% Cu) and to the isolated outcropping galena-fluorite mineralisation in quartz-phyric lava/intrusive at 387720mE, 5355425mN (three samples ranging from 0.3% - 1.1% Pb). Elevated Cu values are more widespread with values of up to 1.4% Cu (from 387900mE, 5354030mN), but, more commonly 0.1-0.4% Cu.

7. CONCLUSIONS & RECOMENDATIONS

7.1 Beatrice Prospect

Results from the work at Beatrice have been encouraging with wide intervals of highly anomalous zinc intersected in two of the four holes drilled during the reporting period (best results of 0.8m @ 8.77% Zn, 2.15% Pb, 105 ppm Ag from 459.3-460.1m in MS10 and 68.4m @ 0.49% Zn, 0.21% Pb and 7.8 g/t Ag from 515m- 583.4m in MS8). Despite the amount of drilling done to date, there remains room (> 400m strike length) in the main Itat Creek zone, footwall to the interpreted Itat Creek Fault, for a zone of significant mineralisation. This zone is currently being tested by DDH MS11 (being drilled underneath MS1). Apart from the large MMI anomaly in the western part of the grid (section 6.1.2), future work at the Beatrice prospect will be dependent on the results of DDH MS11.

An honours project by Marcus Hope (CODES) is due to be completed in November and results from this research may give some added focus to the exploration.

A study on the electrical properties of the Itat Creek Shale (and incidentally any other shales of Western Tasmania) may assist in defining the electrical nature of these spurious responses and consequently result in fewer "false-alarms" leading to drilling of anomalous shale electrical responses. Purchase of a core conductivity meter (approximately $3200) would assist with this task. All core from drillholes at the prospect would be logged and measurements made of the inductive (EM) and galvanic (resistivity from IP surveys) responses. Unfortunately a meter is not readily available that enables chargeable response to be measured easily in hand specimen.

7.2 West Sedgwick.

The top of the Central Volcanic Complex is exposed at the West Sedgwick prospect and this key horizon has been explored spasmodically for over forty years. Despite all the exploration completed here there is still untested near surface potential in the northern area beneath scree and glacial moraine cover. Various geophysical surveys in the southern portion of the prospect has sterilised the potential for a near surface (<150m) conductor however the depth potential (>150m) has only been tested in the Agglomerate Hill and Zig Zag Hill area.

It is recommended that the top of the CVC be MMI sampled with soil samples collected on 200m spaced lines at 25m centres. This programme will involve the rehabilitation and cutting of approximately 46 line kilometres of grid and the collection of 1800 samples for MMI analysis.

In the northern part of the West Sedgwick area the location of the contact between the volcanics and the Owen Conglomerate (Great Lyell Fault) is poorly located. The grid in this area should be mapped before sampling commences to ensure that there is not excessive

sampling over the Owen Conglomerate. There may also be some benefit in using a cheap geophysical technique (VLFEM or SP) to locate the Great Lyell Fault before sampling commences.

7.3 Lake Dora – Lake Spicer.

Mapping and rock chip sampling over this zone have largely confirmed the interpretations and results of previous workers. The overall geology, with no obvious host horizon and mainly Tyndall Group lithologies, the style of alteration, a narrow zone of pervasive, but variable intensity, chlorite±magnetite with minor sulfides, and the nature of the mineralisation, narrow sulphide±magnetite veins, are not consistent with the presence of a large tonnage VHMS orebody of the type Pasminco is targeting in Western Tasmania. No further work can be recommended in the Lake Dora – Lake Spicer area at this time.

8. EXPENDITURE

Total expenditure for all work undertaken by Pasminco Exploration within the Queenstown North Project area (EL's 24/96, 6/98 and 20/98) for the twelve-month period to the end of October 1999 was **$881,047**. A summary of the expenditure breakdown is given below:

Personnel	227,692
Travel and Accommodation	27,037
Geological Consultants	31,075
Geochemical Consultants & Assays	27,325
Geophysical Surveys & Contractors	102,938
Other Contractors	86,040
Drilling Contractors	247,666
Stores & Supplies	9,040
Vehicles Plant & Equipment	4,348
Land	6,045
Computing	3,732
Office	28,014
Administration Fee 10%	80,095
Total Project Expenditure	**$881,047**

LEGEND

Cambro - ordovician:

- Ocg — Owen Conglomerate - pink siliciclastic sandstone and conglomerate

Cambrian:

- Vcg — Volcaniclastic Conglomerate. (Dora Conglomerate): Massive pebble to cobble conglomerate. Rounded clasts dominated by quartz-phyric volcanics with lesser quartzite (Precambrian) and quartz-sandstone/ conglomerate. (Sticht Range Beds)
- Vcss — Volcaniclastic sandstone: (Dora Conglomerate) Quartz-crystal sandstone-rich units within and at base of Dora Conglomerate
- V1 — Massive green grey Quartz-eye volcaniclastic sandstone; Quartz phenocryst-rich (to10mm diameter) rare lithics
- V2 — Massive, grey-green, Quartz-phyric volcaniclastic sandstone-conglomerate. Lithic clasts common (dominantly felsic volcanics but minor quartzite) Weathered rock has knotty appearance. Grades into V1 with decreasing lithic content.
- V3 — Massive to brecciated green-grey Quartz-phyric siliceous volcanic (?lava) Quartz phenocrysts much less abundant and smaller than in V1 and V2.
- V4 — Green-grey feldsapr-quartz-phyric volcaniclastic sandstone; massive, well cleaved; lithic rich in part (felsic volcanics + minor quartzite)
- V5 — Massive orange-green weakly feldspar-phyric siliceous volcanic
- Qfp — Massive to flow banded Pink-green quartz +/- feldspar lava/intrusive
- hbfp — Massive brown-pink-green feldspar-hornblende-phyric intrusive
- Srb — Well bedded grey siliciclastic sandstone with lesser conglmerate and siltstone. Some volcanic clasts near contact with overlying volcaniclastics (Sticht Range Beds)

ALTERATION LEGEND

- Mt. Veined
- Mod-Strong Cl.Altn. (>cl3)
- Py +/- other sulfides
- Hematite altered
- Silica + kfeldspar altered

Structural Symbols

- Strike and dip of cleavage
- Strike and dip of bedding, facing unkno
- Strike and dip of bedding, facing known
- Fault

Topography

- Vehicular track

MINERALOGICAL REPORT No. 7666

by Ian R. Pontifex MSc.

August 13th, 1998

TO :	Dr Barry Murphy Regional Exploration Manager Pasminco Exploration GPO Box 1291K MELBOURNE VIC 3001
YOUR REFERENCE :	Order No. 2504
MATERIAL :	Mineralised rock sample, Mt Read Volcanic Belt, Tasmania
IDENTIFICATION :	B1
WORK REQUESTED :	Polished thin section preparation, petrographic/mineragraphic description and report.
SAMPLES & SECTIONS :	Returned to you with this report.
DIGITAL COPY :	Enclosed with hard copy of this report.

PONTIFEX & ASSOCIATES PTY. LTD.

B1 **Crudely layered vitric-lapilli-tuff, with (deuteric) silica-chloritic-alteration, and minor k-spar. Incorporates 'syngenetic' irregular fine interfragmental networks of sphalerite >> galena, trace marcasitic-pyrite. Rare gold.**

This thin section (and handspecimen) viewed macroscopically is seen to consist of a crudely layered, unsorted fragmental aggregate of greyish and greenish grains/fragments, <1mm to 10mm maximum dimension, with a minor, irregular, but widespread and intergranular fine network of reddish brown sphalerite.

Petrographically, the host rock is seen to consist of various (textural) manifestations of mostly extremely fine granular quartz (25-30%), chlorite (35-40%), and k-spar (10%). [The k-spar is highlighted stained yellow on the section offcut by sodium cobaltinitrite solution.] There are also minor shredded streaky foliae of sericite (7-10%). Ore minerals are sphalerite (approx. 10%), galena (?2%), pyrite <1%.

Most chlorite is extremely fine, gradational to indefinite chloritic-clay, or palagonite, forming patches and crudely aligned lenses to 5mm, with somewhat shredded margins and incorporating minor extremely fine grains of quartz. This material appears to represent altered volcanic glass. Quartz occurs as clusters of extremely fine grains, with a matrix of the chloritic material described above, also forming irregular fragmental patches to several mm across, and as disseminations. Much of this material also appears to be altered (?devitrified) volcanic glass fragments. A small proportion of the quartz, as relatively more concentrated micromosaic, forms apparent individual (volcanic) fragments 1 to 2mm size.

Extremely fine k-spar also forms small, irregular scattered and somewhat shredded fragments, but on small clast 1 to 10mm, of diffuse k-spar micromosaic (see stained offcut), has dispersed sericite and is largely enveloped in shredded foliae of sericite. This sericitic envelope extends to a lens of finer (felsic) tuffaceous fragmental, completely sericitised. Sinuous shredded fine foliae of sericite occur locally through the aggregate.

Dark reddish-brown (translucent) sphalerite occurs as individual grains <0.2mm, more extensively as ragged irregular lenses and stringers forming a discontinuous network between the patchy-fragmental volcanic components described. Minor very fine sphalerite is

incorporated within some fragments. Galena rarely forms individual grains to 0.5mm, but mostly galena occurs as irregular short stringers and irregular grains intricately within sphalerite, also mostly <0.5mm in size. Trace very small (<0.1mm) grains of "marcasite-pyrite" are loosely associated with sphalerite. A single grain of gold, about 20 micron size, occurs on the margin of sphalerite, in a composite sphalerite-galena vein which tends to cut across the gross weak layering in this rock, and this may represent mobilisation of the inherent sulphide.

Interpretation

This sample is identified as a glassy pyroclastic (flow) rock, "vitric-lapilli-tuff", in which the silica, chlorite and possibly the k-spar are basically indigenous, deuteric alteration products of largely original glassy volcanic material. The incorporated sphalerite and lesser galena are also regarded as indigenous (syngenetic). The gross fabric and minor sericitic foliae, and minor apparent recrystallisation/mobilisation of sphalerite and galena into more or less crosscutting veins, are probably due to superimposed low grade metamorphism. [It may be interesting to speculate why the only gold grain occurs in this sulphide vein.]

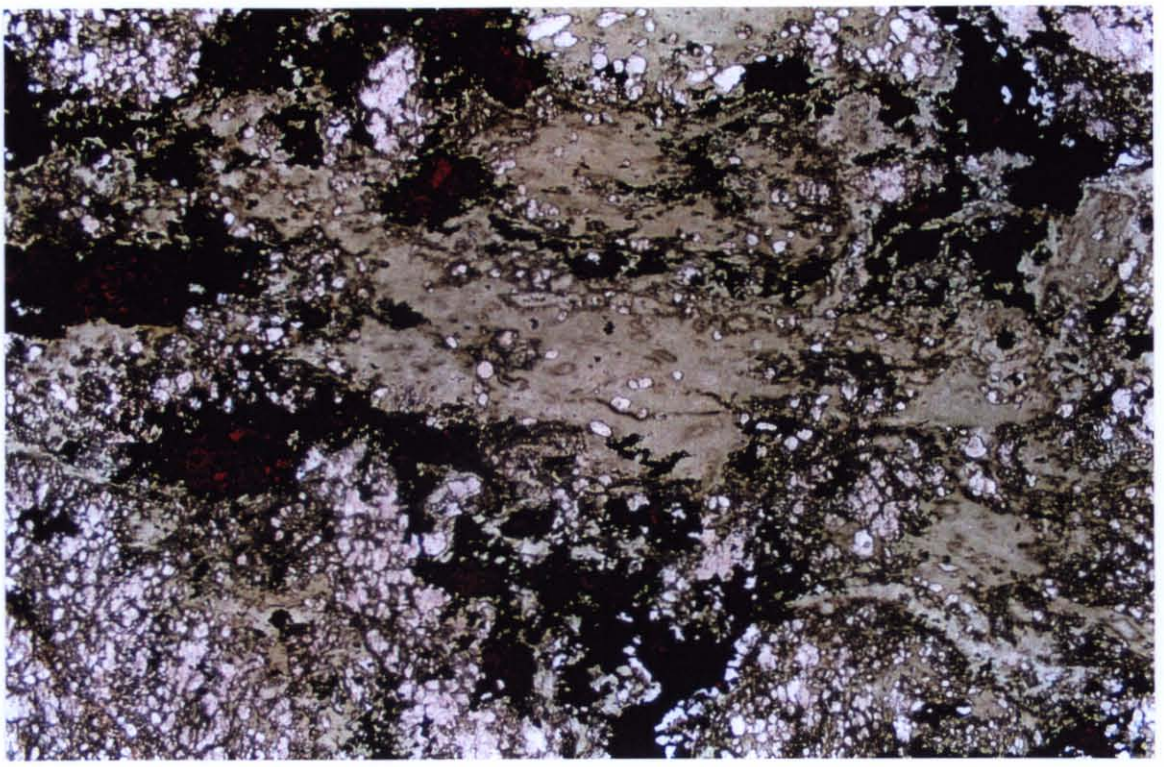

Fig 1 **B1** 0.45 mm

TS. Ordinary light (OL). Shredded lenses of extremely fine chlorite (to palagonite), probably altered glassy fiamme, within a matrix of extremely fine quartz with indefinite clays, also interpreted as altered glass, all constituting an apparent vitric-lapilli-tuff. Dark reddish-brown sphalerite as an integral part of the gross matrix.

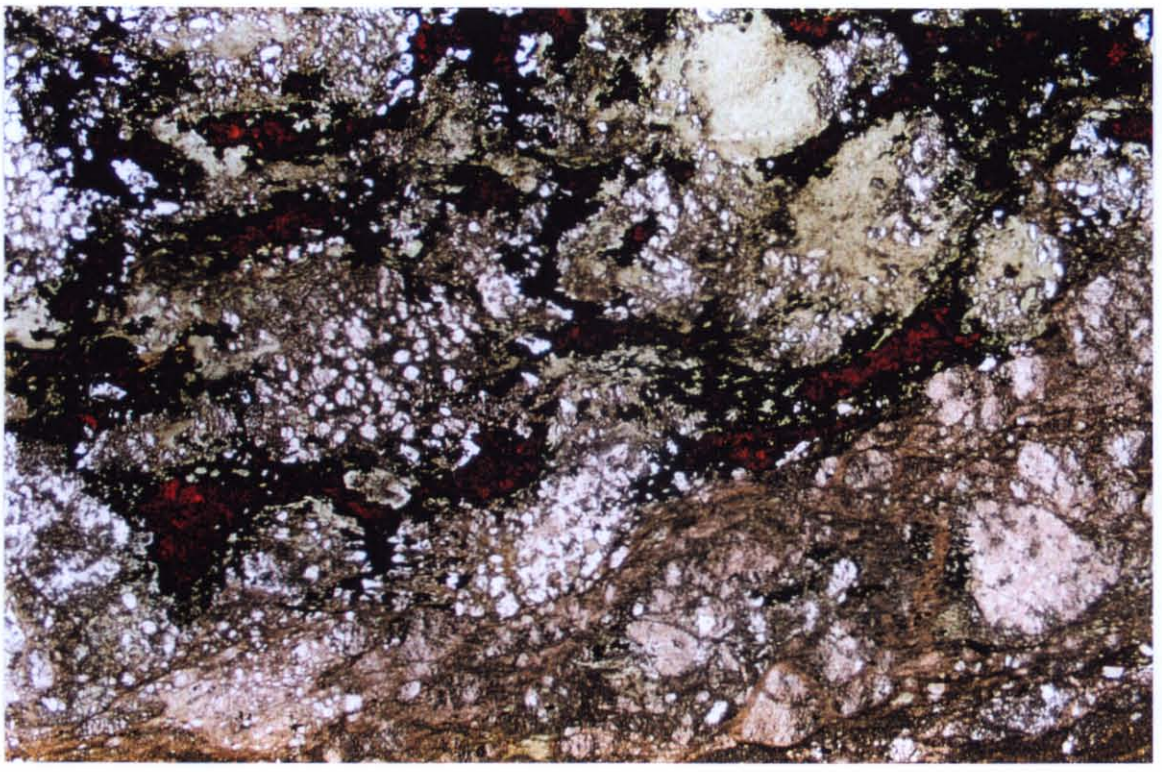

Fig 2 **B1** 0.45 mm

TS. OL. Example of heterogeneous aggregate of chloritic and quartzose ash, lapilli fragmental material. Matrix with shredded foliae and lenses of indefinite alteration products, but incorporating reddish-brown sphalerite with the same integral fabric.

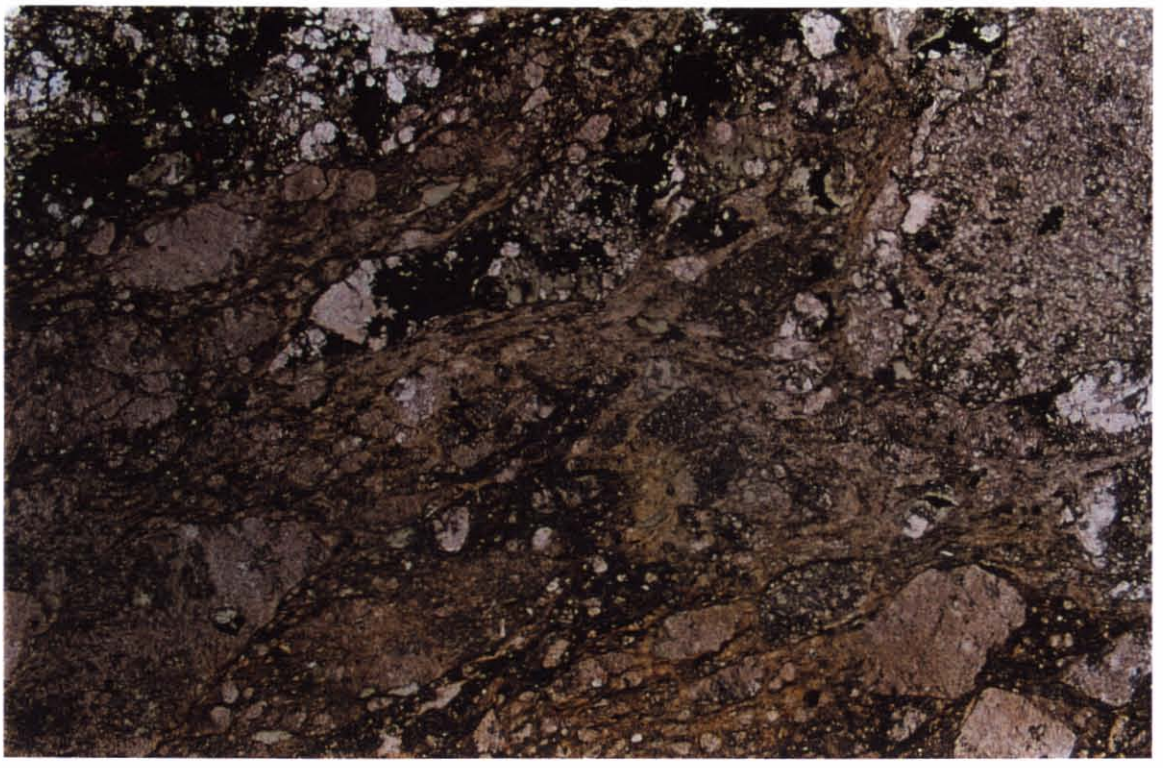

Fig 3 B1 0.45 mm

TS. OL. Local area of crudely layered tuff within a weakly schistose matrix of shredded foliae, incorporating small irregular grains of dark red brown sphalerite (NW quadrant). Larger fragment in NE corner is diffuse, cryptocrystalline k-spar.

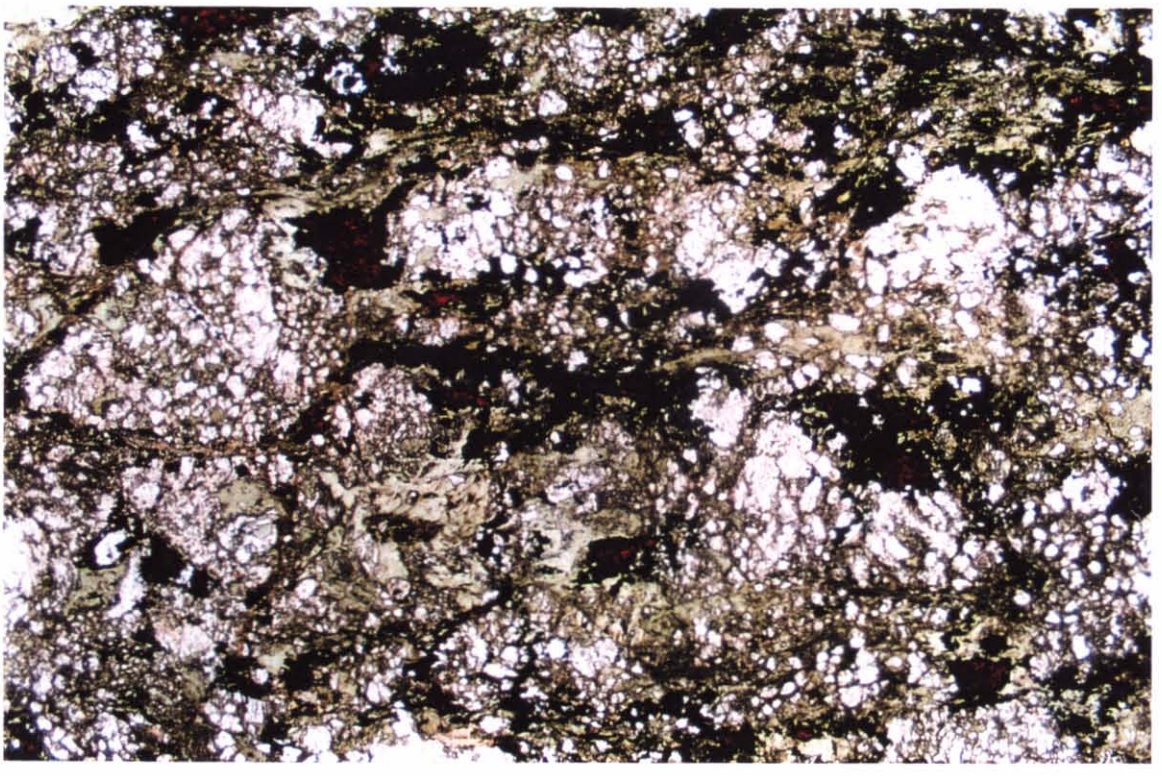

Fig 4 B1 0.45 mm

TS. OL. Further example of tuffaceous host rock, with intricately mixed chloritic material (greenish) and quartzose domains (clear), incorporating scattered dark sphalerite.

Fig 5 B1 0.18 mm

MINERALOGICAL REPORT No. 7703

by Ian R. Pontifex MSc.

October 14, 1998

TO : Mr Kim Denver
Pasminco Exploration
PO Box 886
BURNIE TAS 7320

YOUR REFERENCE : Order No. 1522

MATERIAL : Mineralised rock samples, Mt Read Volcanic Belt, Tasmania

IDENTIFICATION : 274753 to 274761 (x8)

WORK REQUESTED : Polished thin section preparation, petrographic/mineragraphic description and report, including photomicrographs.

SAMPLES & SECTIONS : Returned to you with this report.

PONTIFEX & ASSOCIATES PTY. LTD.

SUMMARY COMMENTS

Eight mineralised rock samples are described in this report from polished thin section, with selected photomicrographs. The lithologies represented all have a volcanic component. Almost all (except 274761 which is different from all others), contain sparse fine to coarser, and locally abundant sphalerite (which is yellow-brown transluscent with apparent relatively low iron content). Galena, pyrite and chalcopyrite occur in several samples, generally less abundant than the sphalerite.

The most intensely mineralised sample is 274758 with semi-massive base metal sulphides within a fairly coarse, pyroclastic flow rock, with extensive chlorite clay-sericite siliceous and carbonate alteration, notably of ex-glassy (pumice) material. [This sample is most like the previous sample B1 described for Barry Murphy, August 1998.]

The bulk rock mineralogy in most samples is compact extremely fine silica, clay-sericite, or sericite-alone, lesser chlorite, commonly with ultrafine dispersed k-spar which is highlighted stained yellow on the offcuts stained with sodium cobalti nitrite. In some samples, it is difficult to positively distinguish this material as mudstone facies, from possible completely altered volcanic groundmass material. Broader macrostructures however are helpful in the regard, variously identifying several samples as lapilli tuffs, and as volcaniclastics (possibly reworked tuffs).

Also, there is a rather distinctive but poorly defined "aggregate-texture" in 274753 and 274757, which may be a pelletal or intrabrecciated mudstone, or a mudstone disrupted by pressure solution process (including the development of stylolites), or possibly lapilli tuff of altered volcanic groundmass material. Regardless, there are definite scattered volcanic fragments including (?derived) microphenocrysts in these two rocks, (similar to volcaniclastic material) and these fragments are altered to composite fine quartz, chlorite, sericite and to adularia ± sphalerite.

INDIVIDUAL DESCRIPTIONS

274753

Bulk rock of clay-chloritic/sericitic composition, possibly (silty) mudstone with vague intrabrecciation structures, or possible lapilli tuff of altered acid lava groundmass material. Numerous scattered discrete volcanic components as quartz-chlorite-(adularia) altered ash fragments, rarer quartz microphenocrysts. Minor sphalerite scattered, slightly coarser sphalerite, plus sparse galena, pyrite, occurs in some altered fragments. Compares with 274757.

Approximately 70% of this rock consists of compact, extremely fine, mixed clay-sericite with minor chlorite and disseminated quartz silt to fine sand size grains. This material incorporates a vague aggregate of subrounded small breccia-clast-like domains, 1mm to 10mm across, some defined by stylolites. Ultrafine k-spar occurs in some areas as indicated, stained yellow on the offcut treated with sodium cobalti-nitrite. Objectively, and alone, most of this material is somewhat non-descript, and could be interpreted as massive mudstone with the micronetwork defining intraformational brecciation or description due to pressure solution. Alternatively, it may represent an aggregate of altered acid-glassy lapilli. Notwithstanding, there are numerous discrete scattered volcanic components forming the other 30% of the rock, manifest as :

*	Rounded quartz microphenocrysts, 0.1mm to 0.7mm	5-7%
*	Irregular fragments <1mm to 3mm of composite, intricately mixed, alteration phases of fine chlorite, quartz, adularia ± clay sericite, with relict aphyric micro-texture, indicative of intermediate (to possibly basic) lava. Some fragments are elongate and apparently fractured fiamme	15-20%
*	Accessory single felspar laths and possible shards	2-3%

Sulphides are also scattered as irregular grains as fine as 0.05 mm to fine granular irregular, patchy lenses 0.5 x 2.5 mm, individually in the general clay-sericite mass, also specifically located within some of the quartz-chlorite altered volcanic fragments. Sphalerite is most abundant (overall about 3% of the whole rock), as transluscent yellow-brown grains. Rare galena to 2mm occurs mostly concentrated within one fragments of lava, and trace pyrite accompanies galena and sphalerite in a diffuse patch of fine quartz + chlorite.

645243

Fig 1 274753 0.45 mm

TS. Ordinary light (OL). Domains of compact extremely fine quartz-clay sericite which may be interpreted as lenses of silty mudstone, or a possible lapilli of altered volcanic groundmass material. Incorporates definite volcanic components, as single clear quartz phenocryst, and fragments of quartz-chlorite-adularia-altered volcanic. Small very dark brown spots in matrix and in altered fragments are sphalerite.

TS. Xnic equivalent of Fig. 1

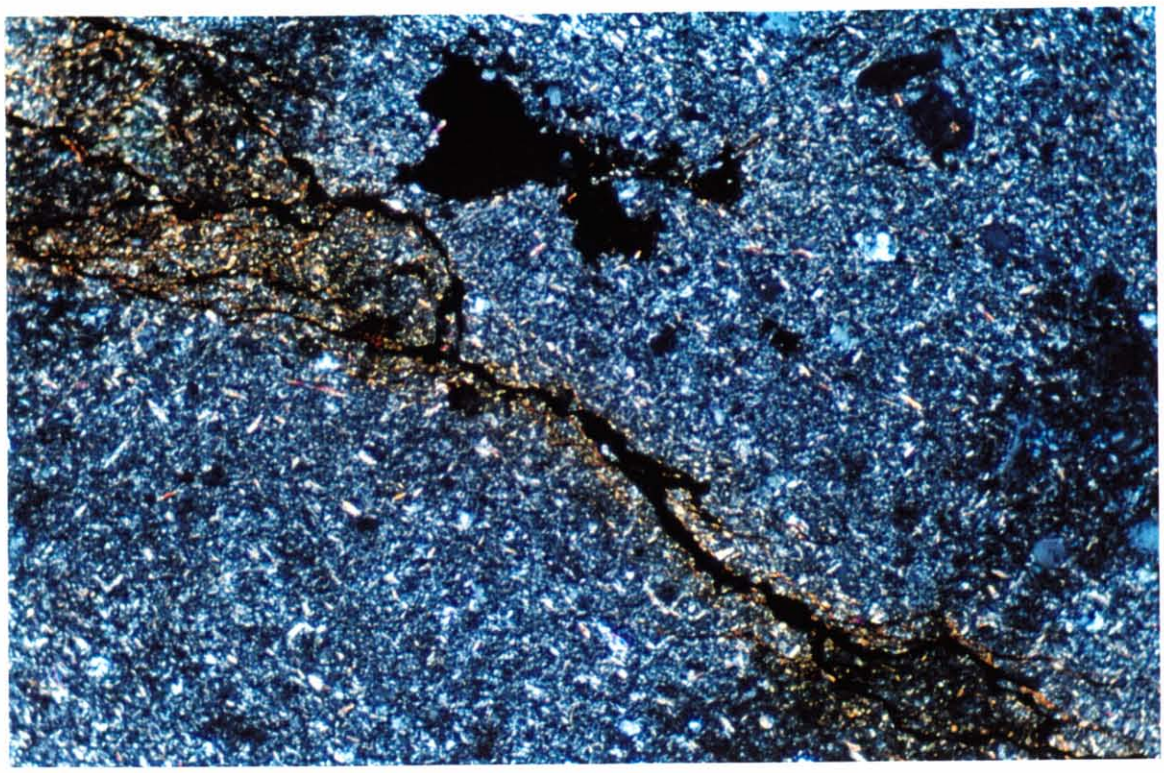

Fig 3 **274753** 0.18 mm

TS. Xnic. Higher magnification of Fig 2, showing detail of massive extremely fine clay-sericite. Black grain is (isotropic) sphalerite. Iron stained microstylolite separates two domains.

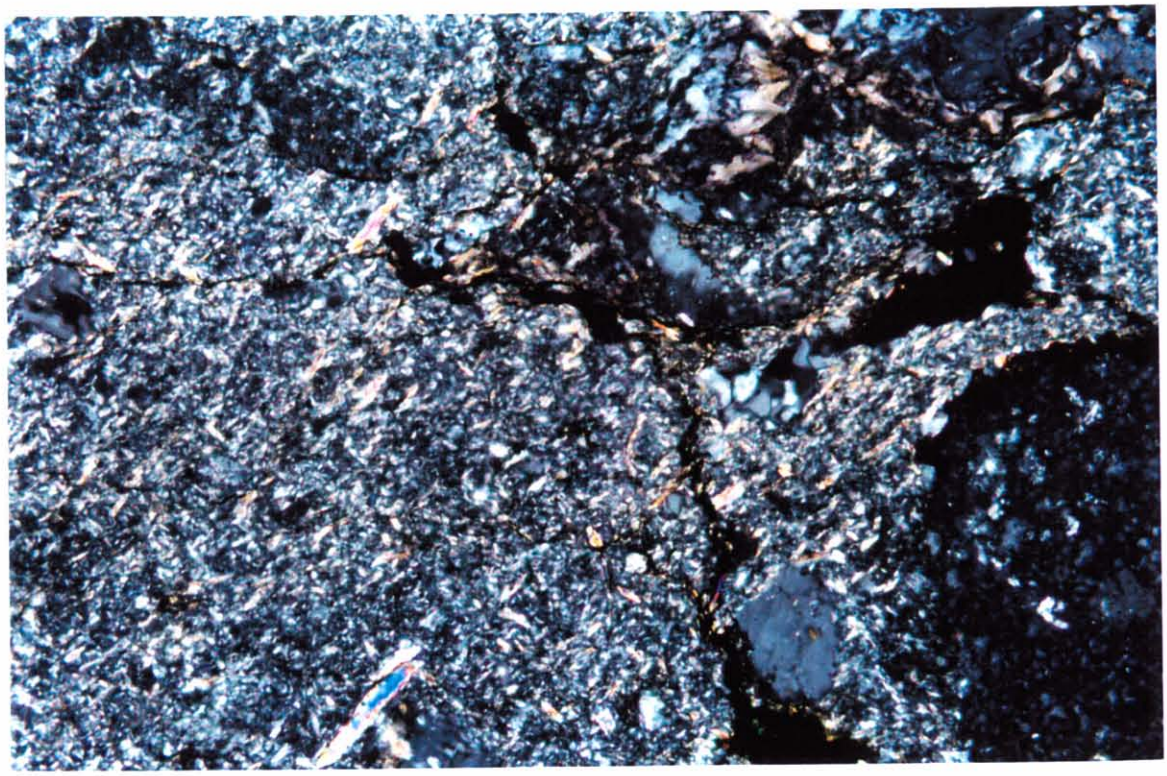

Fig 4 **274753** 0.04 mm

TS. Even higher magnification of Fig 3.

274754

Intermediate to acid pyroclastic-flow rock. Numerous large flow-oriented and clay-sericite-altered, glassy clasts (?pumice) within a sericite-carbonate-quartz microcrystalline matrix. Minor irregular grains and lenses of sphalerite, rarer pyrite, trace chalcopyrite, intricately within the matrix, rarely in veinlets.

Clay-sericite-altered fiamme-like clasts of glass (?pumice) from <1mm in size to 3mm wide x 10mm long are similarly (flow)-aligned, but otherwise irregularly distributed to form about 40% of this rock. These occur within a matrix of microcrystalline quartz mosaic incorporating subordinate patchy/intergranular carbonate, also diffuse patchy sericite, forming about 50% of the sample and apparently representing late stage replacement of a former primary groundmass to the fiamme. Minor subrounded and corroded quartz phenocrysts (5%), <1mm in size, are scattered.

Sphalerite (yellowish-brown translucent) is scattered throughout to form about 7-10% of the whole rock, as very small grains (<0.05mm) to irregular small lenses 0.5mm x 2.5mm, intricately incorporated within the fine quartz-carbonate matrix, rarely in crosscutting short stringers. Trace fine galena > chalcopyrite rarely accompanies this sphalerite.

Pyrite crystals commonly about 0.1mm are locally clustered to form small patches elongate parallel to the prevailing flow direction, and as for the sphalerite, is an integral part of the whole rock, particularly of the alteration groundmass/matrix. Minute inclusions of galena are common in the pyrite crystals.

645246

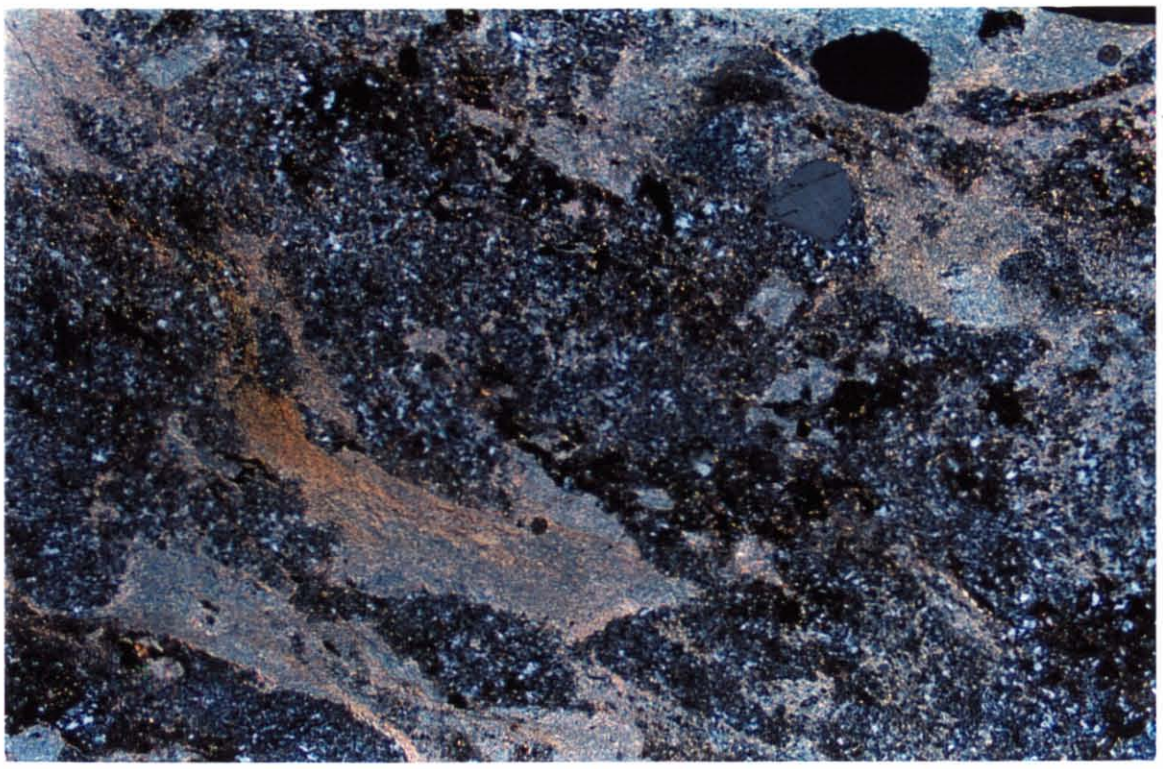

Fig 5 274754 0.45 mm

TS. Xnic. Sericitised elongate clasts of glass (?pumice) and rounded quartz microphenocrysts in silicified/sericitised volcanic groundmass.

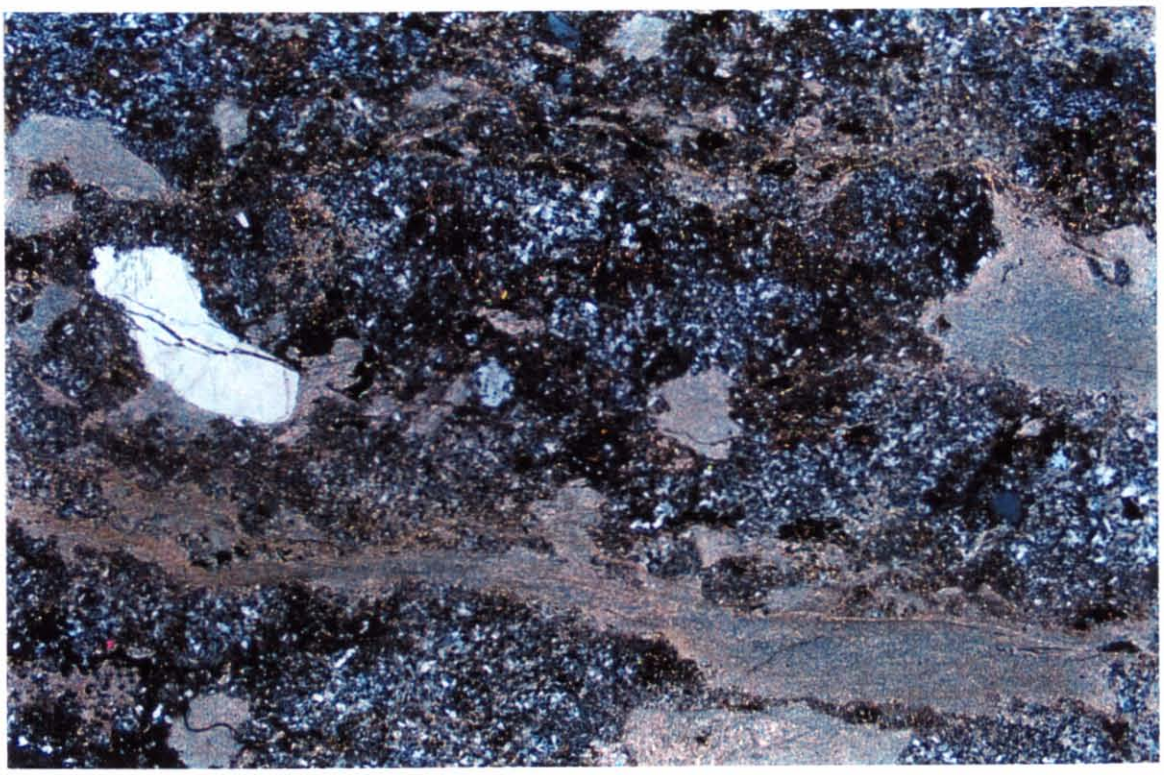

Fig 6 274754 0.45 mm

TS. Xnic. As for Fig 5; small dark patches of carbonate alteration in silicified groundmass.

274755

Irregularly vaguely lenticular-layered silty mudstone, minor scattered sulphide and altered volcanic debris (as in 274753). In contact with an alteration band of ultrafine k-spar ± quartz > chloritic clay, also with scattered (minor) sphalerite > pyrite> galena, trace chalcopyrite and minor volcanic components.

This thin section viewed macroscopically has irregular lenticular-layered areas of extremely fine compact material, variable in colour from dark-grey-green, to mid-grey to pale. Petrographically, the darker domains are seen to consist of variable concentrations of ultrafine chlorite-clay-sericite mudstone/silty mudstone (with detrital extremely fine muscovite), with minor fine scattered volcanic material. This mudstone has accessory small scattered grains of sphalerite ± trace galena (also as in 274753), but numerous stringers of quartz carrying pyrite, chalcopyrite, sphalerite > galena.

This darker domain of mudstone has a variably sharp to diffuse contact with the above, locally with coinciding microstylolites, also with a mid grey 'layer' seen petrographically, (together with the offcut stained yellow by sodium cobalti-nitrite) to consist of massive ultrafine k-spar. This appears to have intricately mixed equally fine quartz, also there are minor scattered micropatches of pale chloritic clay, rare quartz microphenocrysts and scattered, irregular grains of sphalerite > pyrite > galena.

This layer is internally vaguely microbanded parallel to the contact, it is overall about 30mm wide, occupying most of the thin section, and appears to represent a band of extremely fine k-spar ± quartz alteration, presumably developed within an original fine volcaniclastic sediment. Small lithic fragments of altered volcanic material and rare 'phenocrysts' (as in 274753) ± sphalerite are locally loosely clustered.

A vague narrow central core to this band, seen on the offcut to be relatively pale, also with more intense yellow-staining (k-spar-rich) has a small associated patch of composite sphalerite > pyrite > galena.

Total sphalerite content in this rock is about 3%, with pyrite, galena, chalcopyrite each <1%.

645248

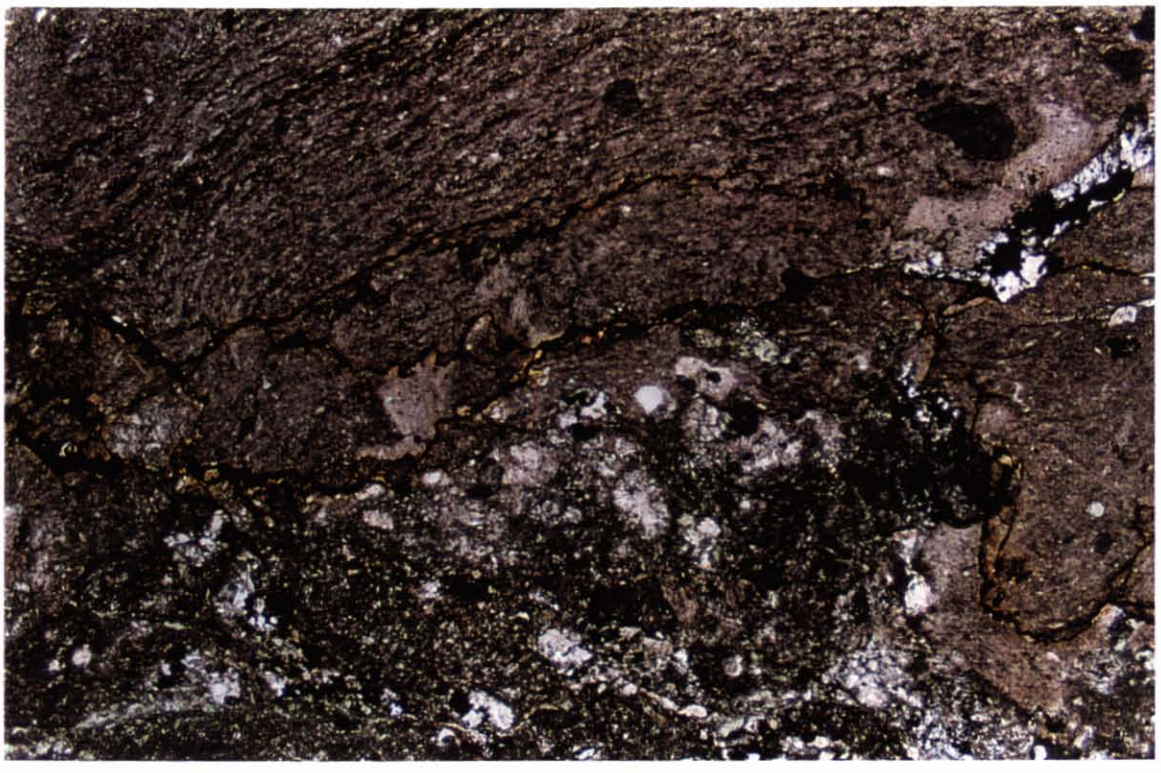

Fig 7 274755 0.45 mm

TS. OL. Contact between apparent mudstone (top) and fine grained volcaniclastic (bottom). Fe-stained microstylolites partly coincide with this contact, dark small discrete grains, loosely clustered are sphalerite, in top right corner sphalerite in a quartz veinlet.

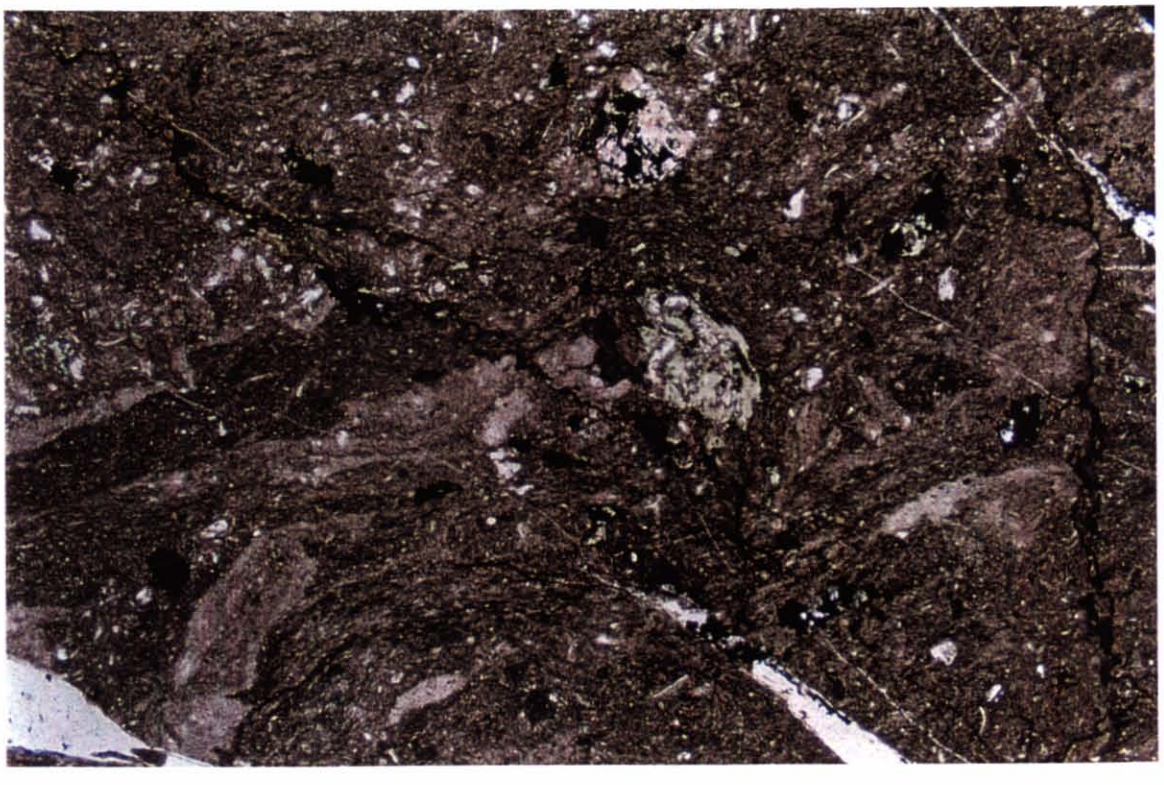

Fig 8 274755 0.45 mm

TS. OL. Mudstone incorporating scattered small altered volcanic fragments. Small black grains of sphalerite disseminated in mudstone, also associated with altered fragments, and in stringers.

274756

Lenticular-layered mudstone including lenses with ultrafine k-spar, and layers with greater and lesser acid volcanic derived detritus (volcaniclastic), selectively replaced by adularia. Minor scattered fine sphalerite > galena, lesser sphalerite in stringers, + quartz.

Macroscopically, this thin section is seen to consist essentially of two major (sedimentary) layers (beds) about 15mm thick, and a very small part of a third layer. Petrographically, an (arbitrary) bottom bed is seen as a fairly homogeneous (chlorite)-clay-sericitic mudstone facies, with minor dispersed silt to fine sand size grains of quartz, several volcanic-derived lithic grains, also sparse fine scattered sphalerite (mostly within a small irregular lens of very fine chlorite).

The (arbitrary) overlying bed is seen on the stained offcut to have ubiquitous ultrafine k-spar (stained yellow), and in thin section, it is seen to consist of several lenses, all with a basically mudstone matrix as in the bed 'below' but with various concentrations and size of scattered, lithic detritus of acid volcanic derivation up to 50mm size (as may be expected in a volcaniclastic sediment). Much of this detritus is selectively and distinctly altered to/replaced by adularia. Accessory small grains of sphalerite from <0.02mm to 0.5mm are scattered, and the rock is cut by several threads and stringers of quartz, some dominated by sphalerite. Several grains of galena to 0.5mm occur in irregular small patches of vein quartz.

TS. OL. Detail of mudstone areas, separated by stylolite; tan-coloured sphalerite in a patch of chlorite alteration.

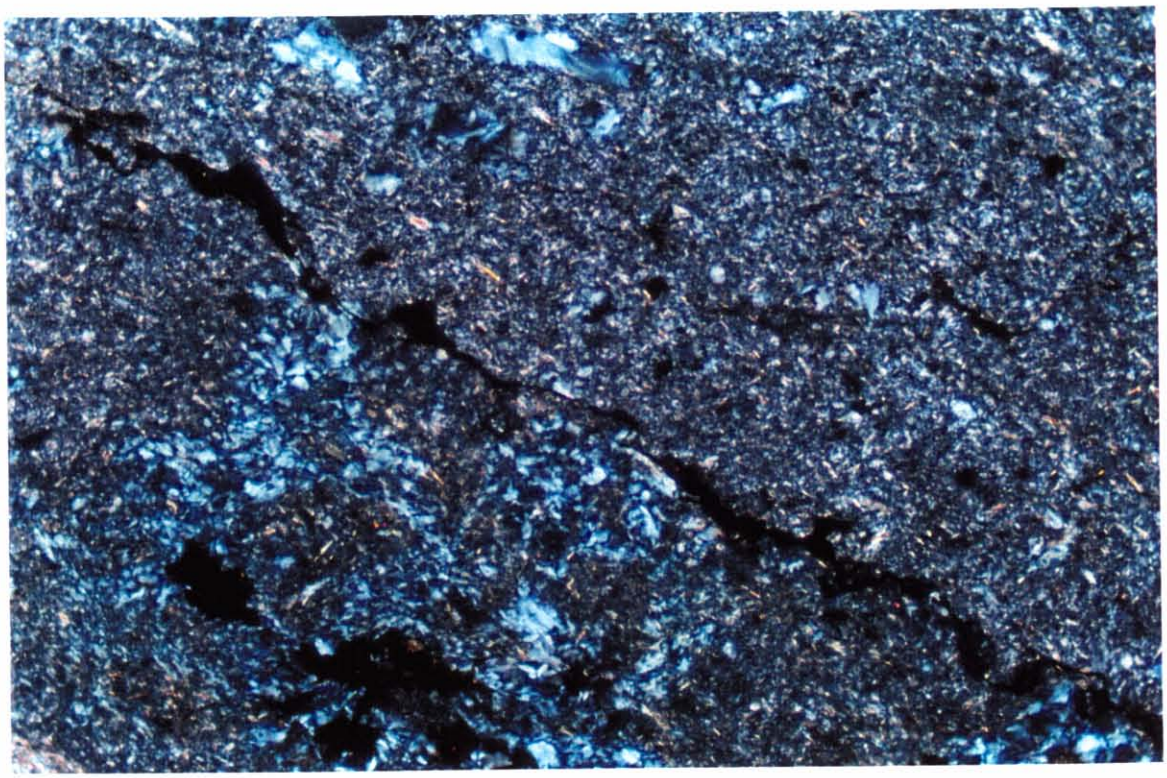

Fig 12 274756 0.18 mm

TS. Xnic equivalent of Fig 11.

274757

Rock with bulk composition mostly extremely fine clay sericite, with an 'aggregate-structure' which may be intraformational breccia within a mudstone, or lapilli tuff aggregate. Minor to locally abundant scattered volcanoclastic detritus. Ultrafine k-spar through some beds, fine quartz-chlorite-adularia alteration of the volcanic material. Minor fine sphalerite separately in mudstone, accompanying some altered detritus and in rare quartz stringers.

This stained offcut shows one layer minimum thickness 20mm dominated by clay-sericite but with ubiquitous ultrafine k-spar, and scattered adularia-altered ash fragments. This has a wavy but sharp contact against another layer of grey similarly fine clay-sericite, without the dispersed ultrafine k-spar, but with minor scattered k-spar altered volcanic fragments. An irregular network of microfissures on a scale of 10mm, including microstylolites occurs throughout the rock, to produce an aggregate structure as in 274753, which may be an internally disrupted mudstone (by pressure solution effects) or possibly it may be a lapilli tuff of altered volcanic groundmass material. The irregular contact between layers may be due to localised microslumping.

This facies incorporates up to 25% scattered volcanically-derived detritus, including sparse rounded quartz micro-phenocrysts and chlorite-quartz-adularia composites. There are sparse fragments of cryptocrystalline-siliceous rhyolitic groundmass material.

Sphalerite as grains 0.05mm to rarely 2mm are scattered throughout to form about 2% of the whole rock. These grains occur independently and apparently inherently in the mudstone, but sphalerite also occurs within several of the chlorite-quartz-adularia altered fragments, some along or on stylolites, and sparse sphalerite also occurs in crosscutting quartz stringers. In other words, sphalerite has apparent syngenetic, authigenic and epigenetic (mobilised) modes of occurrence.

645253

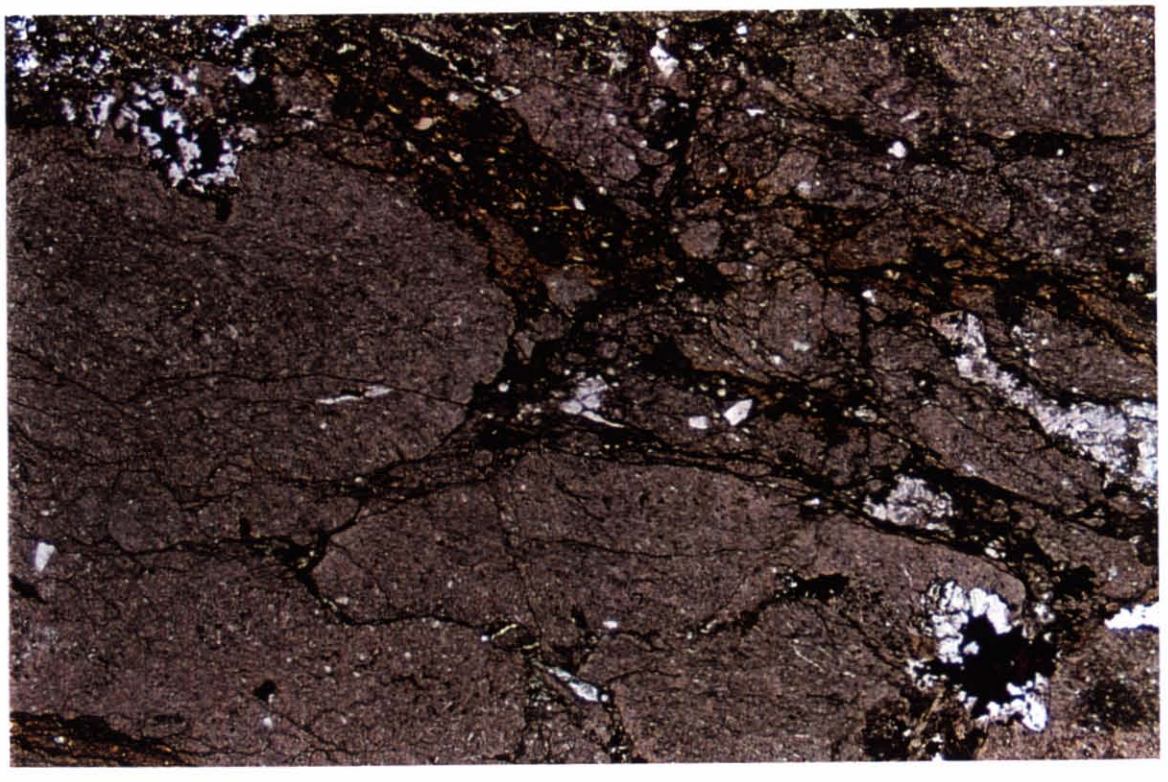

Fig 13 274757 0.45 mm

TS. OL. Domainal area (as in 274753) which may represent massive mudstone internally disrupted in-situ by pressure-solution (including development of stylolites), or by intraformational brecciation. Or possibly this structure represents ash-lapilli of altered volcanic groundmass material. Note red-brown sphalerite localised in clear quartz, also minute disseminated grains of sphalerite.

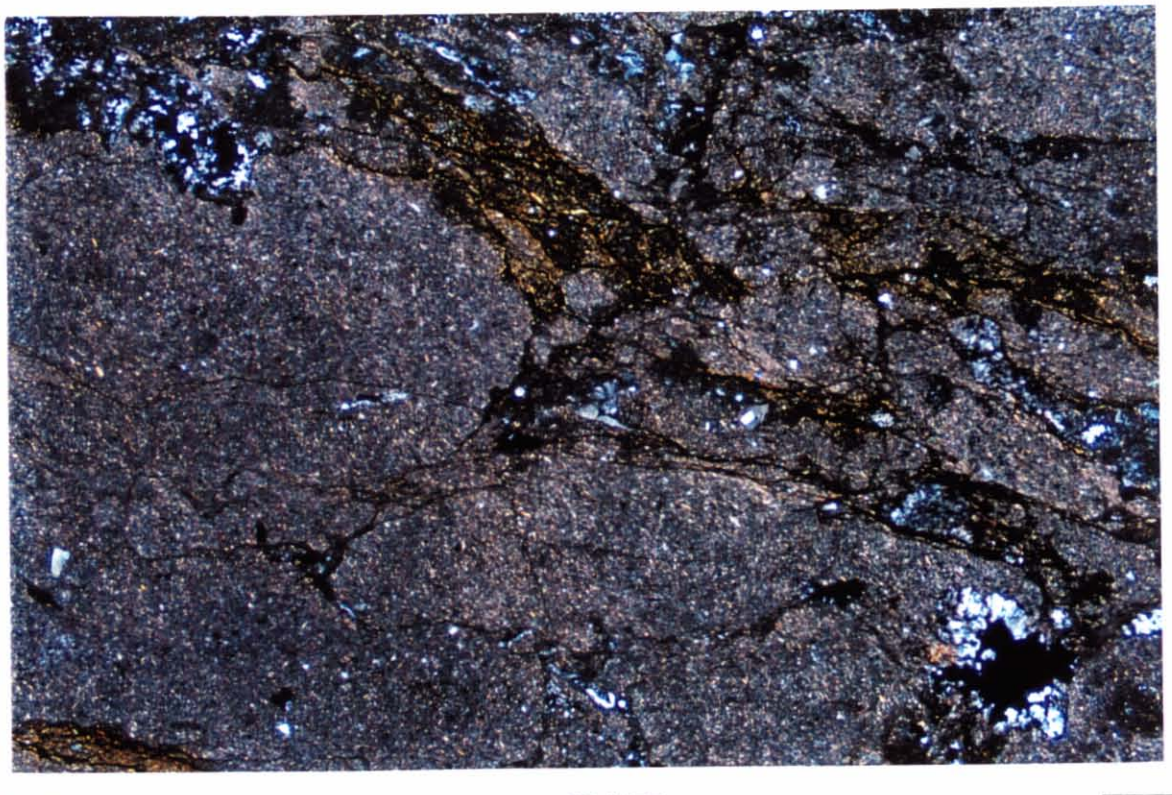

Fig 14 274757 0.45 mm

TS. Xnic equivalent of Fig 13.

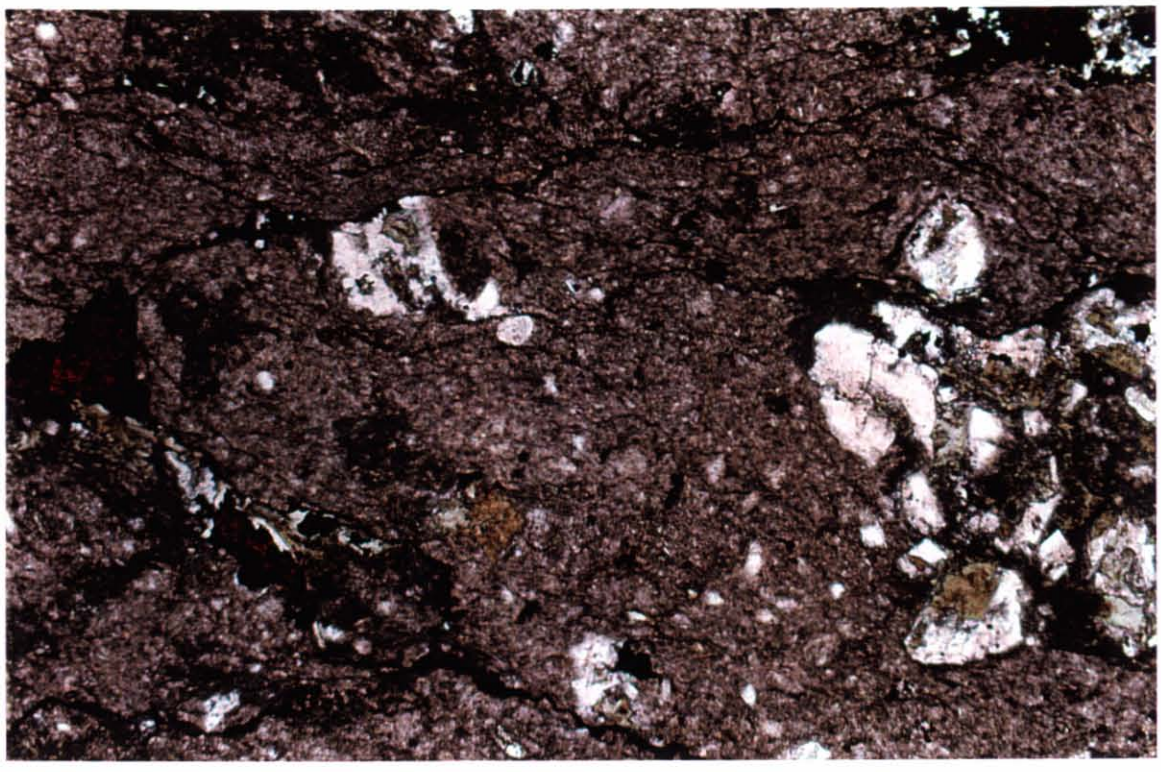

Fig 15 274757 0.18 mm

TS. OL. Higher magnification in Fig 14, including altered volcanic fragment. Red-brown sphalerite in microfissure.

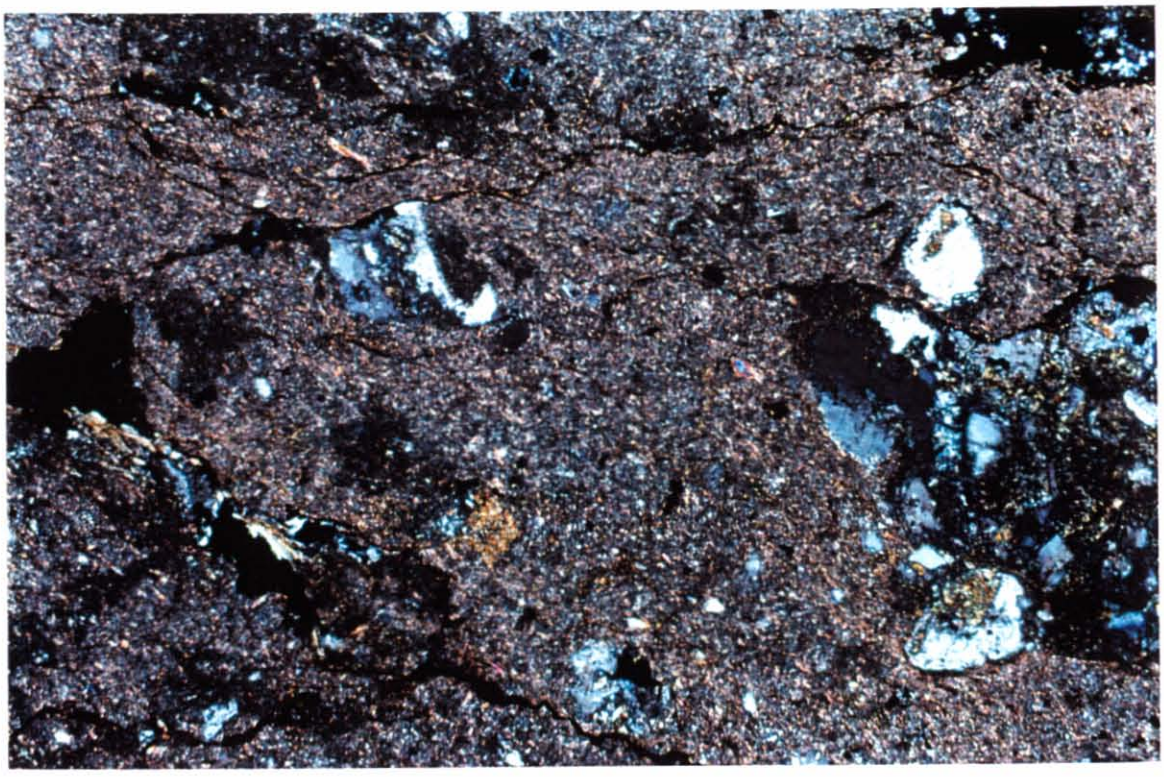

Fig 16 274757 0.18 mm

TS. Xnic equivalent of Fig 15.

274758

Irregularly lenticular-layered apparent glassy (vitric)-lithic pyroclastic, with inherent silica-sericite-chlorite alteration, incorporating semi-massive, intricately intergrown pyrite, galena, lesser chalcopyrite > sphalerite, mostly with associated carbonate. Compares with previous sample B1 (but with carbonate).

This is an apparent altered pyroclastic with a heterogeneous irregular lenticular-layered structure incorporating semi-massive sulphide mineralisation. It is the single sample in this suite most like sample B1, previously described for Barry Murphy, Pontifex Report 7666, 31/8/98, except that it contains carbonate as part of the alteration, more pyrite, no k-spar, and gold was not seen in this sample.

The sulphides and their approximate abundances are :

*	Pyrite ± minor marcasite	15%
*	Galena	10%
*	Chalcopyrite	5%
*	Sphalerite	3-5%

These sulphides are commonly composite, intricately intergrown in patches, less commonly they form crosscutting discontinuous veins and stringers ± carbonate.
Alteration and other non-ore domains are :

*	Extremely fine chlorite, in shredded to streaky lenses, apparently replacing glassy clasts pumice) as an essential pyroclastic component.	20%
*	Extremely fine sericite and clay-sericite, (some intricately mixed with chlorite) also replacing separate streaky lenses of ex-glass. Some incorporate minor quartz micromosaic and quartz microphenocrysts. [Some of these lenses are almost indistinguishable from the shaly-mudstone in other samples described above.]	15-20%
*	Carbonate, fine granular/crystalline mosaic, (?ankerite or siderite) in irregular lenses between and partly within the phyllosilicate lenses, also commonly intricately intergrown with sulphides.	10-15%
*	Quartz micromosaic, rather diffuse and irregular, at least partly original (rhyolitic) lava groundmass material as indicated by the scattered quartz microphenocrysts, but a microfelty texture also indicates secondary silicification.	20%

645256

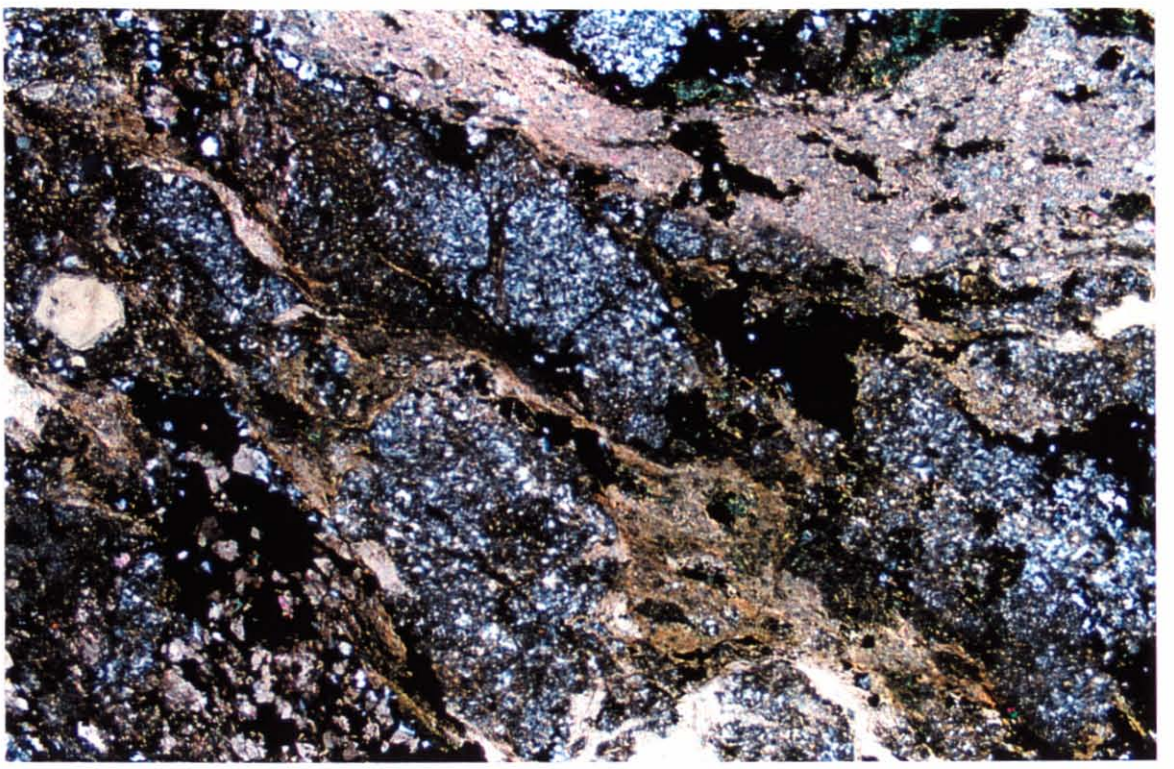

Fig 17 **274758** 0.45 mm

TS. Xnic. Shredded lenses of sericitised and chloritised fiamme, or pumiceous fragments within extremely fine silicified matrix. Cluster of black opaque sulphide with carbonate SW corner.

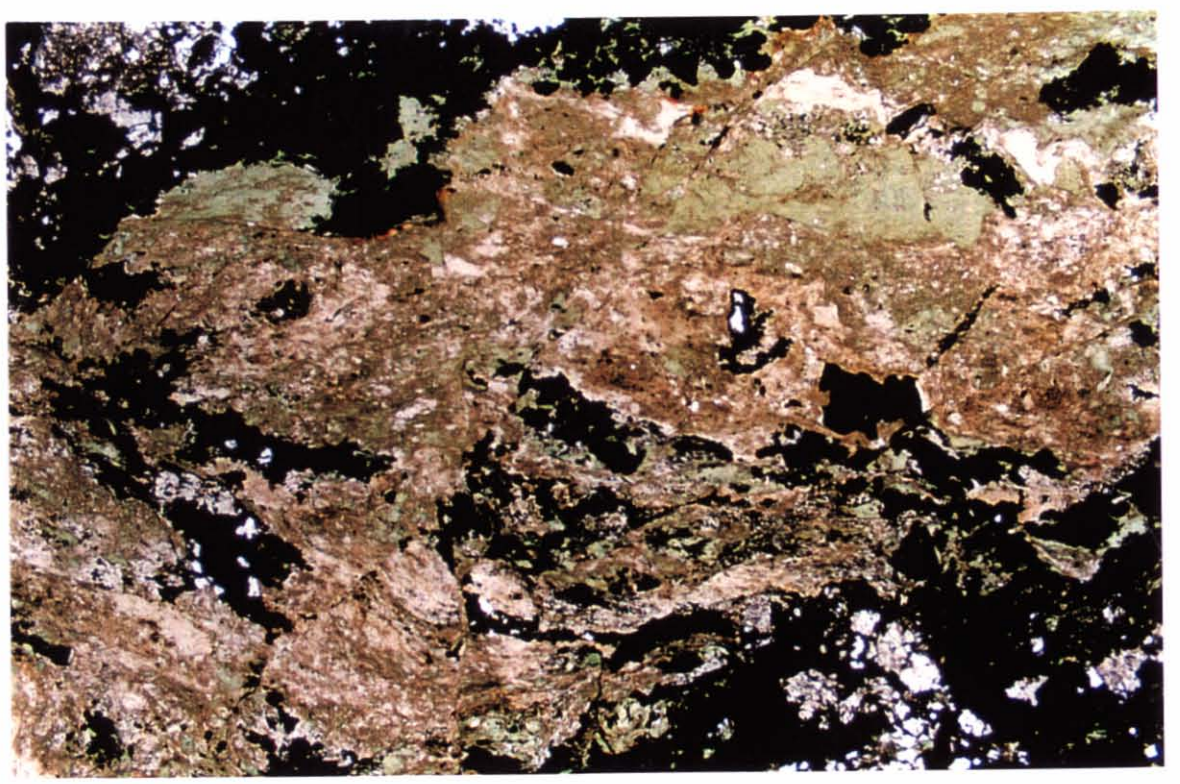

Fig 18 **274758** 0.45 mm

TS. OL. Chloritised fiamme (?pumice) with sulphides.

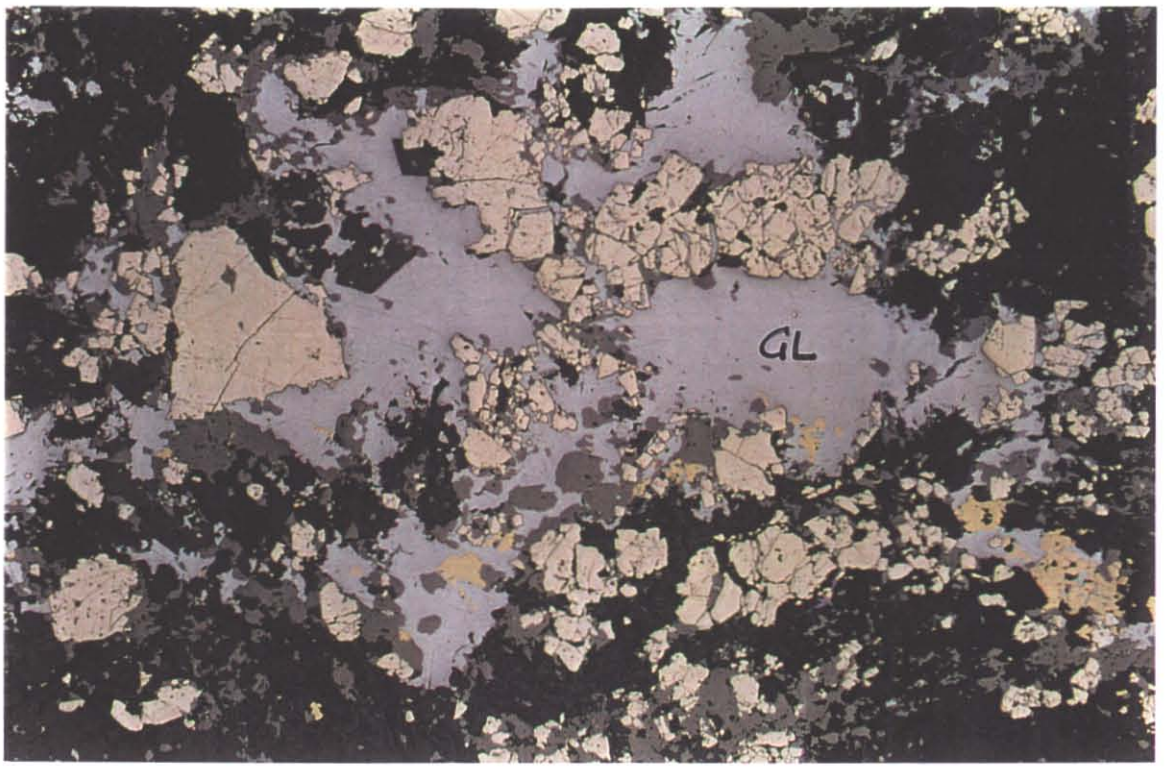

Fig 19 274758 0.18 mm

Polished section, general field, patchy galena GL, scattered/clustered pyrite crystals, minor localised sphalerite (dark grey grains around margins of galena).

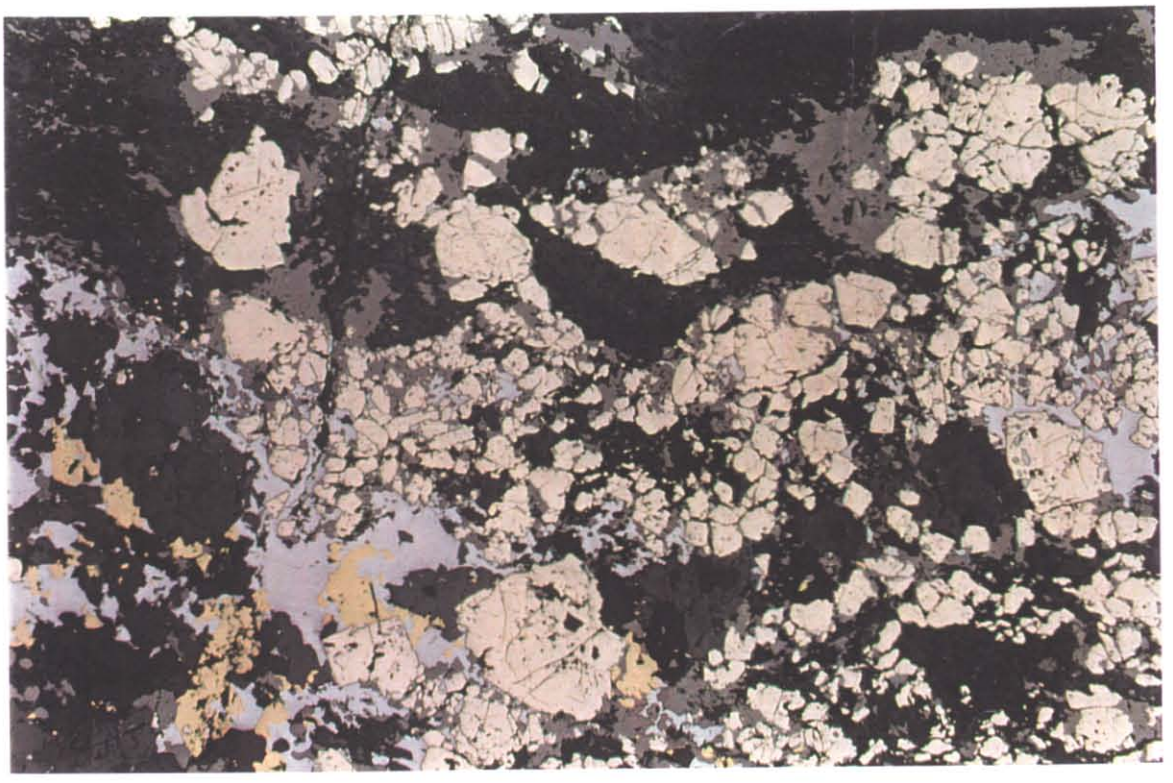

Fig 20 274758 0.18 mm

PS. Basically as for Fig 19.

274759

Irregular aggregate of massive sphalerite composite with carbonate gangue, also crowded with pyrite >> galena. All within an altered acid volcanic groundmass of extremely fine quartz clay-sericite, with minor scattered quartz microphenocrysts. Fine sphalerite along a vague microfoliation in this host rock.

This small sample consists of an irregular amoeboidal-shaped lens 20 x 30mm of fine massive sulphide + carbonate gangue, within an extremely fine, pale, quartz-clay-sericite host rock, which appears to consist of a single continuous coherent domain of altered lava (also with minor fine scattered sulphide).

The sulphide consists of irregularly patchy massive sphalerite (yellow to orange translucent crowded with abundant, scattered, fine to coarse grains of pyrite >> galena. An essential carbonate gangue (ankerite or siderite) is locally abundant, composite with these sulphides (mainly with sphalerite). Only rare-trace fine chalcopyrite is evident in sphalerite.

The host rock consists of extremely fine and somewhat diffuse siliceous micromosaic, crowded with intricately intergrown, equally fine and weakly schistose/shredded clay-sericite (± rare chlorite). This incorporates up to 10% scattered quartz microphenocrysts which appear to be in-situ, with inherent corroded margins. There are also accessory very small (<0.5mm) grains and lenses of sphalerite, similarly aligned along the vague prevailing microfoliation, and apparently inherent to the host altered volcanic groundmass.

645259

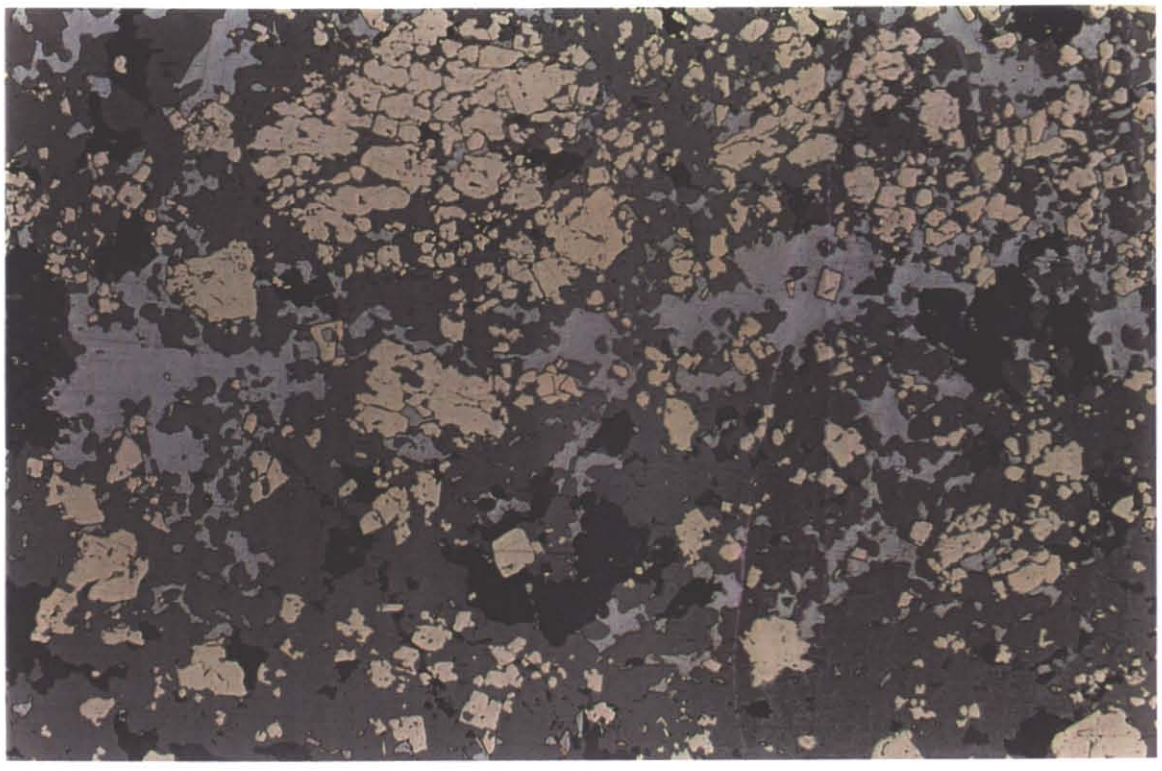

Fig 21 274759 0.18 mm

PS. Background is sphalerite, crowded with abundant pyrite crystals and irregular galena grains.

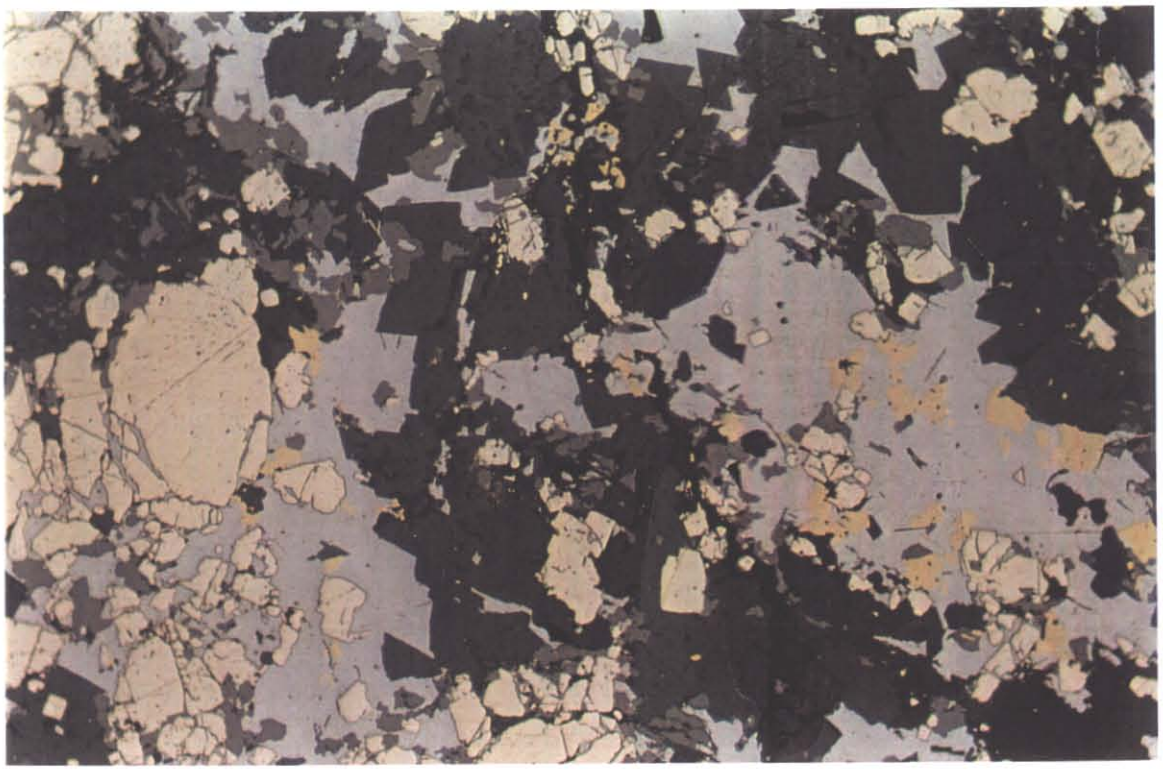

Fig 22 274759 0.09 mm

645260

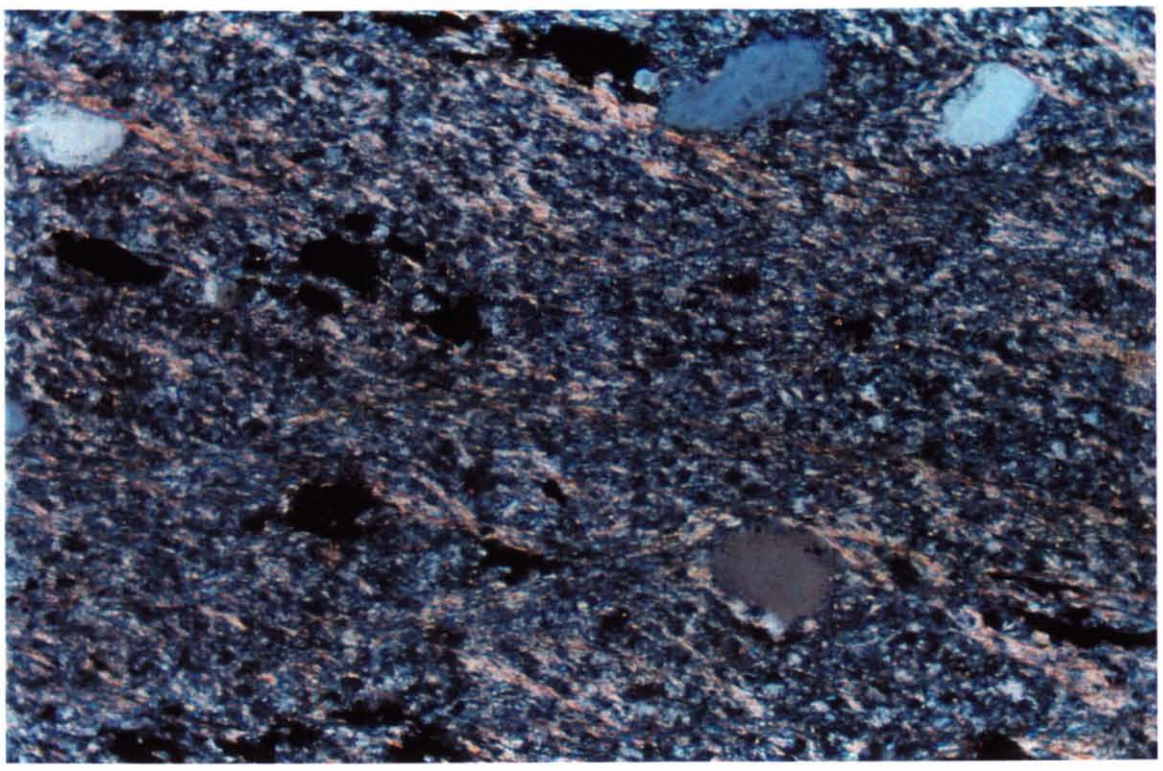

Fig 23 274759 0.09 mm

TS. Xnic. Host rock to sulphide aggregate, interpreted as silica-clay-sericite altered acid volcanic with quartz microphenocrysts, black scattered grains of sphalerite.

274760

Microlayered (fine bedded), clay-sericite-rich silty to medium grained, acid volcaniclastic sandstone. Minor pyrite, trace extremely fine sphalerite and galena in some layers.

This is a fairly homogeneous, pale grey, fine grained rock with a microlayering obvious in handspecimen (and in thin section). The offcut treated with sodium cobalti-nitrite shows greater and lesser very fine discrete grains of k-spar stained yellow, and a more diffuse weaker staining through the ultrafine (muddy) matrix.

Petrographically, these fine k-spar grains (0.05 to 0.2mm) also numerous quartz grains, lithic grains and lesser carbonate grains of similar size are identified as being derived from an acid volcanic, possibly representing reworked tuff. These all occur in variable concentration in different layers, representing volcaniclastic fine bedding, within clay-sericite, lesser chlorite and ultrafine silica almost certainly of the same derivation, but with a very weak metamorphic microfoliation defined by short threads of sericite. Minor fine pyrite crystals (total 2-3%) and trace much finer sphalerite > galena is scattered through several of the fine beds. There is a single crosscutting veinlet of fine crystalline pyrite.

This fine bedded volcaniclastic, silty to medium grained sediment, which has a very similar gross composition as other volcanics and mudstones together with mixed volcanic components in this suite. In some of these other rocks, the chlorite-clay-sericite-carbonate ± sulphide, represents primary in-situ alteration, in this rock (and in 274755, 756), these components appear to have been basically derived, albeit conceivably from previously altered volcanics.

645262

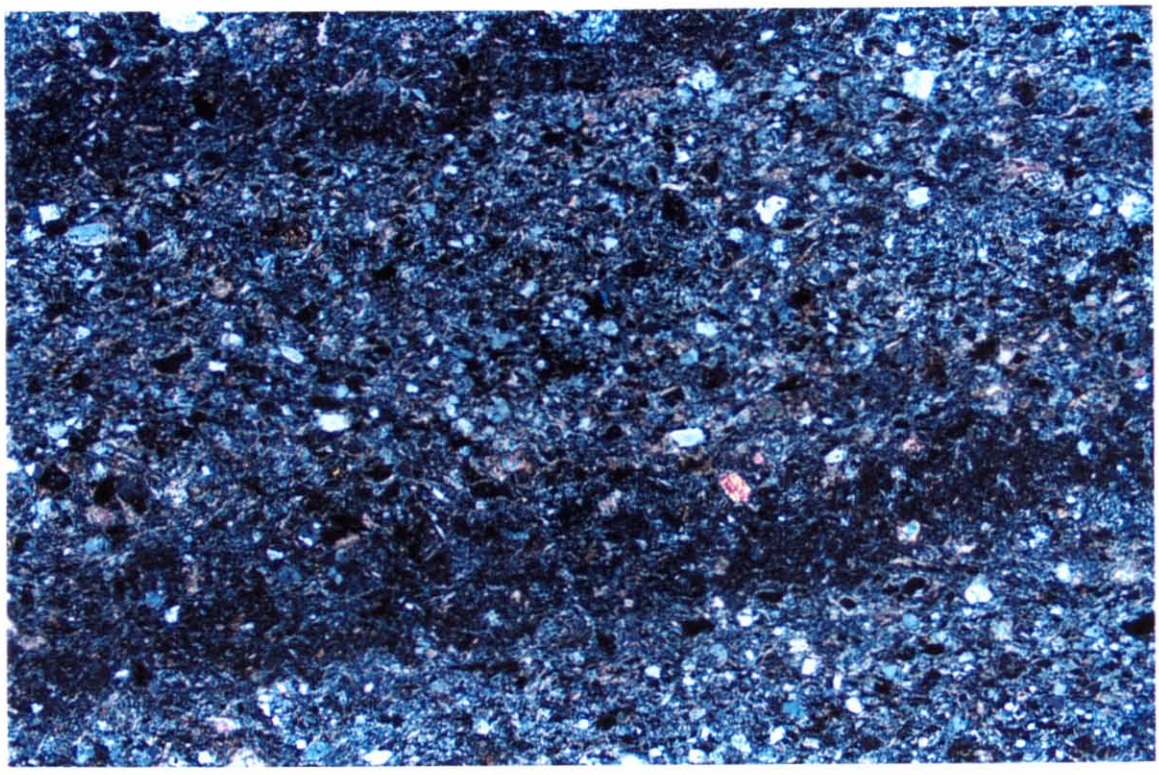

Fig 24 274760 0.45 mm

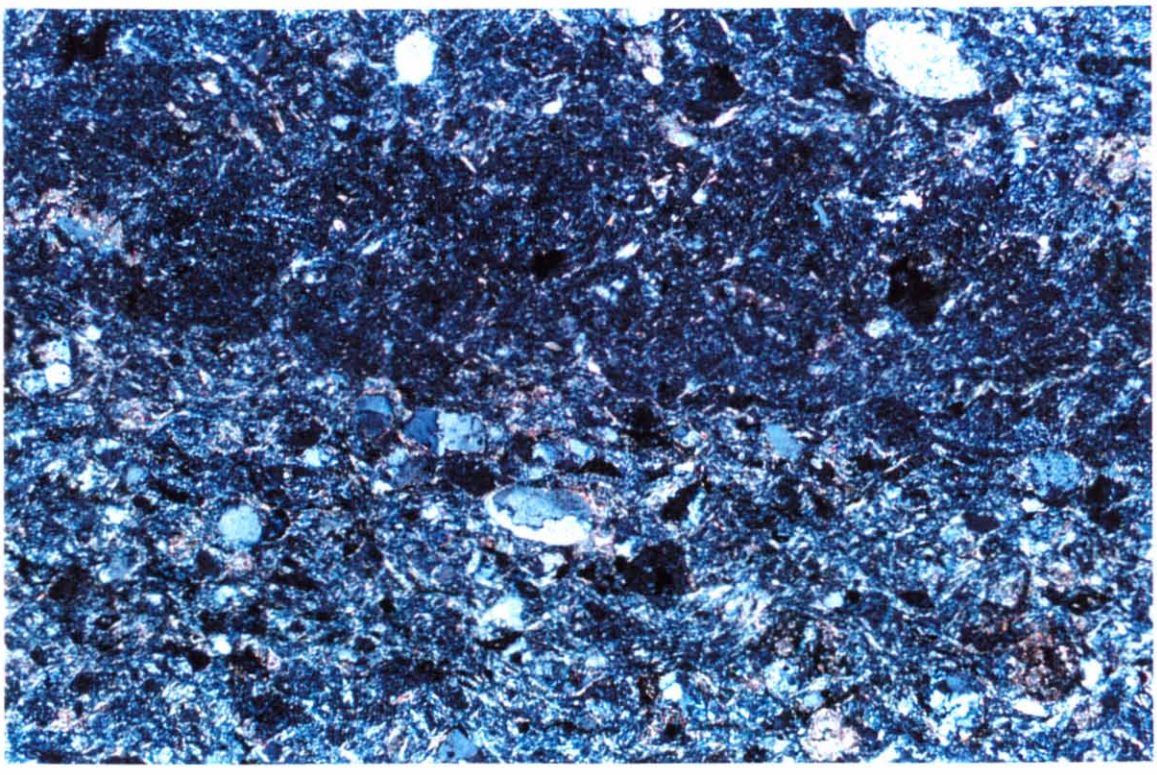

Fig 25 274760 0.18 mm

TS. Xnic. Detail of Fig. 24.

645263

274761

Massive acid volcanic groundmass host rock, with original felspar completely sericitised. Cut by major vein, and auxiliary stringers of bladed hematite + quartz, in which the hematite appears to be converting to (pseudomorphous) bladed magnetite. Accessory disseminated martite crystals of rare oxidised pyrite in some quartz stringers.

A vein to 10mm wide of coarse bladed hematite and numerous related but less continuous stringers of hematite form about 10% of this section area, all within a fairly homogeneous, pale, massive and very fine grained host rock. Petrographically, the host rock is seen to consist of a diffuse micromosaic of quartz and intricately mixed clay-sericite, interpreted to represent original quartzofelspathic microcrystalline volcanic groundmass (with ex-felspar now sericitised). There is however no evidence of discrete phenocrysts or related diagnostic textures to positively confirm this interpretation.

The main vein, and the somewhat detached random stringers, also even finer networks of threads, all with abundant micaceous hematite with a crystal size commensurate with the width of the veins. These veins also consist of quartz, all apparently filling and healing fractures. Lesser fine single crystals of granular hematite, (martite after magnetite) are disseminated outside of the veins. Minor small patches/grains and irregular lenses of hydrothermal quartz and/or sericite, without iron oxide(s) also occur sporadically through the host rock, and there are several goethite replicas after small pyrite crystals in some of these.

It is of interest that the bladed hematite, particularly the coarse hematite in the main vein appears to be converting to (pseudomorphous replacement by) magnetite, presumably due to change in partial pressure of oxygen during the final stages of hydrothermal introduction of these veins.

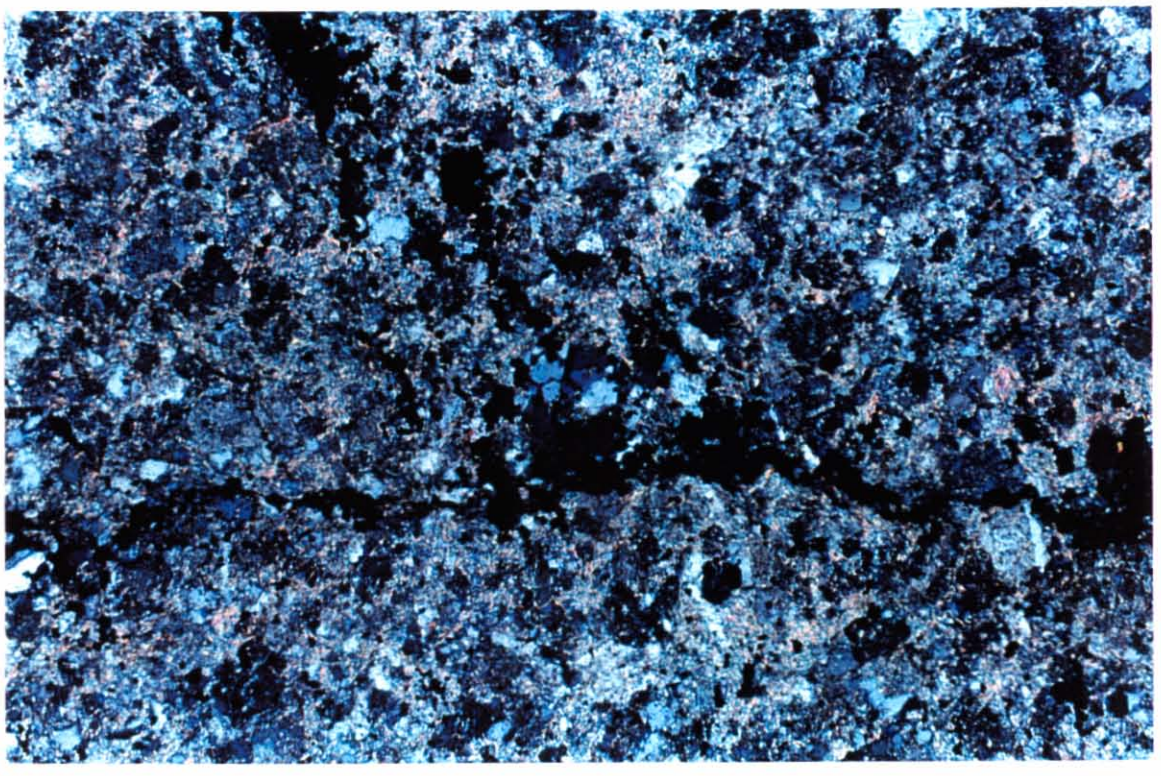

Fig 26 **274761** 0.18 mm

TS. Xnic. Host rock of diffuse quartz/sericitised-felspar micromosaic representing altered acid volcanic, cut by stringers of hematite.

Fig 27 **274761** 0.09 mm

PS. Coarse bladed hematite in main vein, apparently partly converting to magnetite (pale brownish).

1. SUMMARY

During February-March 1999, a total of 8.8 line kilometres of induced polarisation (IP) data using the pole-dipole configuration were acquired at the Beatrice Prospect. The Beatrice Prospect is situated in Western Tasmania within EL 6/98 approximately 7 kilometres north of the town of Queenstown. Data were acquired by Zonge Engineering Pty Ltd under instruction by Pasminco Exploration who are currently exploring the ground for Rosebery style Pb-Zn-Ag-Au mineralisation The aim of the IP survey was to delineate anomalous chargeability and resistivity response that could be attributed to disseminated sulphide alteration and/or direct massive sulphide mineralisation for the purpose of drill target generation.

The pole-dipole configuration was selected to enable suitable depth penetration to facilitate mapping several hundred metres below the surface through a resistive quartz-porphyry unit. The technique allowed relative ease of field acquisition and provided a high signal strength to enable reading eight dipole receiver stations (n=8). A consequence of the large number of receiver stations was relatively slow production. A total of 30.73 days were required to acquire 8.8 line kilometres, equating to 0.3 km's per day (six dipole movements) and costing approximately $AUS7000/km. In future it has been recommended that alternative field procedures are developed to assist with data acquisition.

The survey data were of good quality with high signal to noise ratios encountered for all dipole separations. It is anticipated that larger n spacings (at least out to n=12) would have been theoretically possible, effectively increasing the depth of investigation. Data were inverted using the Zonge IP2D smooth model inversion software and output as depth-sections of depth v's resistivity and depth v's chargeability.

The local geology is relatively well represented in the IP inversion results. Black shale units typically exhibit chargeable and moderately conductive responses in contrast to the siliclastics and porphyry which exhibit resistive and low chargeability response. There are several zones whereby alteration is inferred through deviation of the above expected electrical characteristics of lithological units. Moderately high chargeability and lower resistivity within the porphyry and siliclastics are interpreted to respond to alteration (most likely caused by disseminated pyrite). These are interpreted to exist within an anticlinal fold in the north-east (Line 1800N and 2000N) and in the south-east (Line 800N, 1000N and 1200N) at depth within a porphyry. Several other smaller isolated zones of alteration have been delineated and are defined on interpreted sections within the report.

Recommendations include drill testing of three zones of anomalous chargeability. A target on Line 2000N is situated within favourable geology in the anticlinal hinge below a folded black shale. The second target on Line 800N lies within a porphyry unit and is coincident with anomalous mobile metal ion geochemical results. A third target is defined on Line 1200N just to the west of the Itac Creek Fault position.

2. INTRODUCTION

The Beatrice Prospect is situated within EL6/98 approximately 7 km's north of the town of Queenstown in Western Tasmania (Figure 1.). The ground is currently being explored by Pasminco Exploration for its potential to host Rosebery style Zn-Pb-Ag-Au mineralisation within Palaeozoic volcanics and volcaniclastic sediments of the Central Mt Read Volcanics. The region also has potential for Mt Lyell style Cu-Au mineralisation.

This report presents results of a pole-dipole configuration induced polarisation (IP) survey conducted by Zonge Engineering Pty Ltd (Zonge) for Pasminco Exploration during February-March 1999. The aim of the IP survey was to delineate anomalous chargeability and resistivity response that would be directly associated with sulphide mineralisation, and thus provide targets for further exploratory drilling.

3. LOCAL GEOLOGY AND PREVIOUS WORK

The Beatrice Prospect comprises a prospective horizon of the Cambrian Mt Read Volcanics at the top of the Central Volcanic Complex (CVC). The CVC comprises predominantly felsic volcanics and volcaniclastics and is typically overlain by a sequence of shales, siltstones and sandstones. It is conceptual that this contact provides a focus for mineralisation either by acting as a fluid trap and favourable geochemical site via the overlying shales, or as the sea-floor position for Koroko style VHMS mineralisation deposited during a period of quiescence. A quartz-feldspar porphyry has intruded possibly as a sill along this contact and is a prominent feature of the local geology (the Mt Sedgewick Porphyry). The Ordovician Owen Conglomerate forms topographic ridges and scree slopes that abut onto the prospective ground. Remnants of eroded Permian sediments as horizontal layered clay/silt/sand beds are also evident in the region.

The simplified local geology comprises a gently folded to steeply dipping north-south striking black shale horizon situated at the contact between overlying porphyry and underlying volcaniclastic and felsic volcanic units. The black shale outcrops along a fault expressed along a present day drainage (Itac Creek) and is interpreted to dip steeply to the west and then gently fold to form an anticline in the west underlying the Mt Sedgewick Porphyry. Minor Pb-Zn mineralisation is observed in outcrop and in drill intersections within the black shale and underlying siliclastics. The two areas with potential for further mineralisation are considered to be the steeply dipping shale in the Itac Creek and the extensions of this shale (and ashes-shales-ignimbrites) that underlie the Mt Sedgewick Porphyry to the West and East of Itac Creek.

Exploration to date has focused upon the black shale units that are situated strike parallel with the Itac Creek Fault.

Previous work has been summarised by Denwer (1998) in an unpublished report for Pasminco Exploration. Initial work at the prospect commenced in 1975 with stream sediment sampling and geological mapping. Subsequent work included:

- Establishment of over 40 km's of gridding - 1976-present
- 38 line km's of gradient array IP surveying - 1976
- Additional soil sampling - 1977-78
- Drilling MS1, MS2, and MS3 - 1978
- EIP, DHIP, dipole-dipole, and pole-dipole IP geophysical surveys (SCINTREX) - 1978
- Drilling MS4, and MS5 - 1979
- Ground magnetics, gradient array IP, pole-dipole IP, dipole-dipole IP - 1979
- Fixed loop UTEM - 1989
- Drilling MS06 - 1996

4. SURVEY SPECIFICATIONS

The pole-dipole survey configuration was selected primarily to facilitate measurement of receiver potentials out to at least n=8 (400m) from the transmitter electrode position. The potential voltages measured a distance from an electrode position supplying a current to the earth vary dependent on the array configuration. Dipole-dipole array IP surveying (more generally applied in exploration) has a voltage that drops off more rapidly with distance from the electrode than for the pole-dipole array (Figure 2), hence the pole-dipole technique was selected for this survey (equations derived from Telford 1990). The pole-dipole configuration also allowed the survey to be conducted in mountainous terrain with poor access to grid lines. The remote electrode was positioned along a track with vehicle access (Figure 1) and hence the transmitter was not required to be moved for the remainder of the survey.

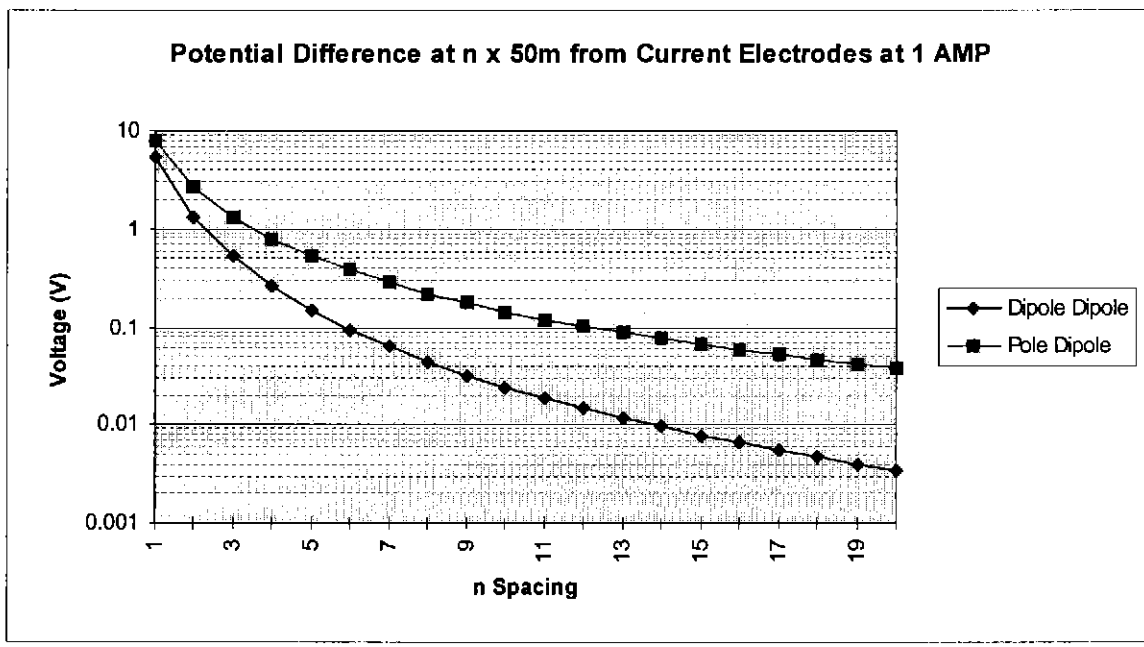

Figure 2. *Plot of the potential voltage that would be recorded on the ground for a homogenous half-space of 5000 ohm.m; input current of 1.0 A; and dipole separation of 50m.*

The survey specifications are tabulated below:

Date of Survey:	February - March 1999
Contractor:	ZONGE Engineering Pty Ltd
Survey Type:	IP
Approx. Line km's:	8.8 km
Line Spacing:	200 m
Configuration:	Pole-dipole
IP Mode:	Complex Resistivity (CRIP)
Dipole Spacing:	50 m
"n" Spacing:	8
Receiver:	GDP32

Transmitter: Zonge 30KW
Contract Number: PASEXP023

The IP parameter is provided as a decoupled phase shift between the input waveform and the received voltage in units of milli-radians at 0.125 Hz.

Porcelain pots filled with $CuSO_4$ saturated solution were used for receiver dipole electrodes. Up to six iron stakes were used at the roving transmitter electrode position, and aluminium foil lined pits at the stationary electrode position (distant electrode for IP). All eight receiver dipoles were read simultaneously for each current electrode position.

The method of data noise and repeatability control was as follows:

- Two readings are taken at each station.
- If the readings lie within 5% error then an average of the two is taken as the result.
- If the readings lie outside of 5% error, then a third reading is taken. If the error lies within 10%, then an average is taken as the result.
- If the three readings lie outside of 10% error, then a fourth reading is taken. If the error lies within of 15% then the average is taken as the result.
- Five readings is specified as a maximum amount to be recorded taking the average values as final data.

A total of 8.8 line km's of data were acquired on five separate lines. Data were acquired on lines 800N, 1000N, 1200N, 1800N, and 2000N. The location of the Beatrice Grid is displayed in the location plan of Figure 1. The location of each acquisition line within the Beatrice Grid is presented in Plan 1-5 also showing pseudosections of IP data. A total of 30.73 days were required to acquire the 8.8 line kilometres, equating to 0.3 km's per day (six dipole movements) and costing approximately $AUS7000/km. This is particularly slow production (a consequence of the terrain and survey configuration). In future it is recommended that alternative field procedures are developed to assist with data acquisition. This would include pre-laying out of multi-strand receiver wire across the entire grid prior to survey commencement.

The survey data were of good quality with high signal to noise ratios encountered for all dipole separations. It is anticipated that larger n spacings (at least out to n=12) would have been theoretically possible, effectively increasing the depth of investigation. This would have effectively doubled the cost of the survey which had already exceeded budget acquiring n=8 data.

5. MODELLING PARAMETERS

IP data were inverted using the ZONGE RS2DIP v2.05h two-dimensional smooth-model inversion software. For future reference, the modelling parameters used for both the IP and resistivity inversions are listed below:

Header(1)='From RS2DIP v2.05h Date:05/03/99 Time:13:37:42',
Header(4)='Observed data from 2000n.avg',
Array='PoleDipole',StnBeg=-2000.00,StnEnd=-500.00,
DipoleLength=50.0,StnPerDipole=50.0,LengthUnits='m',IPUnits='mrad',
NXSplit=3,NZSplit=2,
ARerrFloor=1.0,IPerrFloor=0.1,
NResIter=15,ResSmth=0.50,ResdpW=0.50,ResdxW=1.00,ResdzW=1.00,
NIPIter=15,IPSmth=0.10,IPdpW=0.01,IPdxW=0.50,IPdzW=0.50,
RMSRdat=2.15,RMSRmod=0.89,RMSPdat=1.64,RMSPmod=3.38,

The "defaults" for inversion typically have the ResSmth and IPSmth parameters as 1.0. It was determined through trial and error that the "default" settings were unsuitable, and values of 0.50 and 0.10 were applied for ResSmth and IPSmth respectively. The lower these parameters were adjusted, the less smooth the resultant inversion model. It was found that by lowering these values the following desirable outcomes were achieved:

1. The resultant inverted sections better represented geology as they were less inclined to create large "ballon-like" features often an undesirable characteristic of smooth-model inversions. Sharp geo-electrical boundaries (such as a shale horizon adjacent to a porphyry unit) are typically not well represented by a smooth-model inversion. Lowering the smoothing parameters achieved a better representation of such boundaries.
2. The error levels between the inverted data and the observed data became extremely low. Using the "default" parameters error levels were often above 50% whereas levels with the final parameters are generally less than 10%.

The inversion software also allows adjusting the "smoothness" of the model in the X and Z directions (ResdxW, ResdzW, IPdxW, and IPdzW). For a layered earth (1D) model it is desirable to lower the dzW parameter with respect to dxW. Alternatively for vertical stratigraphy it would be more suitable to lower the dxW parameter with respect to dzW. Unfortunately both geological conditions exist at Beatrice and a compromise was used by keeping these two modelling parameters equal.

6. DISCUSSION AND RESULTS

Data are provided as pseudo-sections of Apparent Resistivity and Apparent Chargeability in Plan 1 to Plan 5 for Line 800N, 1000N, 1200N, 1800N, and 2000N respectively. Common colour histogram stretches and contour intervals have been applied on all plans to allow comparison of data from line to line.

Inverted sections of depth vs resistivity and depth vs chargeability draped on the topography are provided in Plan 6 to Plan 10 for Line 800N, 1000N, 1200N, 1800N, and 2000N respectively. A section displaying the interpreted geology from the IP results is also provided on Plan 6 to Plan 10. Common colour histogram stretches and contour intervals have again been applied to the inversion results to allow comparison of data.

Results are discussed independently for each line below (it is recommended that the corresponding Plan is viewed whilst reading this section):

LINE 800N (Plan 6)

The inversion results from Line 800N feature two main features/targets. These are; (1) centred at -1600E, 450mRL and (2) centred at -700E, 350mRL. Zone (1) is a region of elevated chargeability (up to 50 mRad) within a zone of generally moderate-high resistivity. It is interpreted that this zone represents alteration (pyrite) of the Mt Sedgewick Porphyry and shale unit on the eastern limb of an anticlinal structure. This zone corresponds relatively well with a subtle geochemical anomaly and thus the combination of responses would provide a viable exploration target; -1600E, 450mRL.

Zone (2) is observed at the Itac Creek Fault and is a zone of high chargeability and low resistivity interpreted to be associated with the mineralised black shale observed at this position.

LINE 1000N (Plan 7)

Line 1000N exhibits similar response to Line 800N. The chargeable feature centred at about -1500E at a depth of 400mRL and the response at the Itac Creek Fault associated with the black shale at -750E show good correlation with the response observed on Line 800. The target Zone (1) depicted on Line 800N is slightly less chargeable to the north on Line 1000. The target Zone (2) becomes even more chargeable on Line 1000 than on the Line 800 to the south. The inverted resistivity provides evidence for tight folds just to the west of the Itac Creek Fault (observed at the surface at -700E).

LINE 1200N (Plan 8)

Line 1200N again exhibits a similar response to that observed to the south on Line 800N and Line 1000N. Good correlation is observed in the continuance of the western chargeable zone at depth (centred at -1350E and 450mRL). On Line 1200 this ovoid chargeable zone (interpreted as alteration in the Mt Sedgewick Porphyry and shales) is

situated within the synclinal axis of a broad primary fold. An interesting is that this ovoid chargeable zone has migrated from -1600E on Line 800N to -1350E on Line 1200N. Conversely, a tight fold featured adjacent to the Itac Creek Fault on Line 800N appears to migrate to the east from the south to the north (the fold axis migrates from -750E on Line 800N to -1050E on Line 1200N).

The response below the Itac Creek to the west of the Itac Creek Fault associated with the Itac Creek black shales has become considerably more chargeable and conductive than observed in the southern two lines. Drillholes MS07 and MS02 were collared directly over this position and drilled to the north, hence it has not been tested. This position would provide a valid exploration target; -800E, 550mRL.

LINE 1800N (Plan 9)

Line 1800N inversion results show evidence for a further westward migration of the anticlinal fold that was observed adjacent to the Itac Creek Fault on Line 800N. A broad fold hinge is centred on -1425E. Further evidence for this anticlinal structure is provided in the drilling results from MS05 (collared at approximately -1500E) which intersected shallow shale (60m) underlying the Mt Sedgewick Porphyry. The anticline is shown electrically by a low resistivity zone observed in the inverted resistivity section (Plan 9). This low resistivity zone is confined vertically but extensive laterally and is interpreted to represent a black shale horizon that has been intersected by drillholes MS05 and MS08. Drillhole intersections with the black shale horizon compare quite well with the IP inversion results. This interpreted fold structure is not so evident by the chargeability inversion results. It is not entirely clear why the chargeability inversion does not match the resistivity inversions. It can only be assumed that the chargeability data correspond more to alteration than directly to the shale unit. The inverted chargeability section shows a large bulk of anomalously high chargeability lying within the anticlinal fold favouring the western limb. A geological explanation is that it is conceptual that the high chargeability represents alteration and/or mineralisation underlying the black shale horizon interpreted from the resistivity inversion results. This would provide a good target for further investigation. A viable exploration drill target is provided at -1550E, 750mRL.

The black shale horizon outcropping in the Itac Creek also exhibits anomalously high chargeability and low resistivity. This position has been tested to some degree by MS01 (on Line 1600N) and MS04. Both of these holes were oriented to the west and thus drilled down-dip and cannot be regarded as quality tests of the stratigraphy.

LINE 2000N (Plan 10)

Line 2000N inversion results compare very well with those from Line 1800N to the south. The anticlinal fold structure and underlying high chargeability zone observed on Line 1800N are repeated on Line 2000N. The depths show that the black shale horizon is shallower on this Line 2000N providing further evidence for a southerly plunge on the geology of the region (supported by data from Line 800N-1800N). Again the chargeable

zone in the anticlinal fold is considered to conceptually represent an alteration zone underlying the black shale horizon and thus provide a good exploration target.

The black shale within the Itac Creek again exhibits anomalously high chargeability and low resistivity.

7. RECOMMENDATIONS

Three targets have been recommended for drill testing as a results of the IP survey results. These have been selected following analysis of the survey data and discussion with project geologists.

i) The initial target is defined as the highly chargeable zone lying within the fold hinge interpreted from the resistivity inversion section on the western end of Line 1800N and 2000N. This anomalous chargeability zone is conceptually a zone of sulphide alteration underlying a black shale horizon and thus provides a good target for Zn-Pb-Ag-Au mineralisation based upon mineralisation models accepted for the region. A drill target is defined at -1550E, 750mRL to test this anomaly.

ii) The second target is defined on Line 1200N just to the west of the Itac Creek Fault position. The resistivity and chargeability are particularly anomalous at this position on Line 1200N. Data on Line 1400N and Line 1600N were not collected and it should be kept in mind that the response might improve further to the north on these two lines. The position on Line 1400N should has been adequately tested by MS07 and MS02. A target to test the anomaly on Line 1200N is defined at -800E, 550mRL.

iii)The second target is the zone of high chargeability centred at -1600E, 450mRL on Line 800N. This zone is interpreted to lie within the intercalated Mt Sedgewick Porphyry and shale as a region of sulphide alteration. The base of the black siltstone horizon directly underlying this interpreted alteration zone (if it does exist) would provide a target for Zn-Pb-Ag-Au mineralisation. Conceptually the alteration of the porphyry might represent hanging wall alteration through continuance of expulsion of hydrothermal fluids during deposition or later remobilisation of sulphides from below/within the black shale.

Technical recommendations following completion of the survey are as follows:

i) Field procedures need to be addressed in order to make acquisition of pole-dipole (or dipole-dipole) data more economic. It is recommended that multi-strand wire be purchased and laid out in advance prior to mobilisation of the survey crew.

ii) The acquisition of survey data up to n=8 was integral to mapping the base of the black shale horizon on Line 800N, 1800N, and 2000N. On Line 1000N and 1200N the base of the shale horizon is inferred from the inversion results. If data had only been acquired to n=6 then it is unlikely that the survey would have resulted in confident conclusions as to the geological structure of the region. It is recommended that further acquisition of IP data using large n spacings is warranted. The data quality would have most likely permitted acquisition of survey data out to at least n=12.

1. SUMMARY

The Beatrice Prospect is situated in Western Tasmania within EL 6/98 approximately 7 kilometres north of the town of Queenstown. During April 1999, a total of 4 line kilometres of controlled source audio magneto-telluric (CSAMT) data using the H-polarisation configuration were acquired over two lines at the Beatrice Prospect. CSAMT is a deep penetrating electromagnetic geophysical technique that responds to conductivity contrasts in the sub-surface.

Data were acquired by Zonge Engineering Pty Ltd under instruction by Pasminco Exploration who are currently exploring the ground for Rosebery style Zn-Pb-Ag-Au mineralisation. The survey was conducted with two main aims. The primary aim of the CSAMT survey was to delineate anomalous conductivity response that could be attributed to alteration and/or direct massive sulphide mineralisation for the purpose of drill target generation at the Beatrice Prospect. A secondary aim was to act as a test case for the application of CSAMT to base-metals exploration in Tasmania. For this reason a significant portion of this report and SUMMARY encompasses technical detail for the purpose of technique evaluation. Various processing and modelling algorithms were applied over the data to determine an optimum interpretation procedure to follow when using CSAMT data.

The CSAMT survey was selected to enable suitable depth penetration to facilitate effective mapping up to 1km below the surface through a resistive quartz-porphyry unit intercalated with moderately to poorly conductive black shale units. The technique is well suited to the rugged terrain of Tasmania due to the system configuration which requires only a single transmitter location point. A requirement of the survey is that the transmitter is located some distance (up to 10km) from the survey area. The transmitter for the Beatrice survey was situated to the south-east of the town of Queenstown approximately 8 km's south from the acquisition grid. The system operates by measuring electrical and magnetic fields at the surface as deviations from a plane-wave electromagnetic field propagating through the earth from the transmitter. The electromagnetic field parameters are measured at progressively lower transmitted frequencies at each station effectively increasing the depth of investigation.

The survey data were of generally good quality with high signal to noise ratios encountered for most frequencies. Data acquired at 256Hz were found to be very noisy in places. It is thought that this noise is induced by powerlines (256Hz is a multiple of the 50Hz frequency of the Tasmania power grid) or by a transition to near-field data at this frequency. Problems are sometimes encountered with CSAMT surveys whereby the transmitter is located too close to the survey area and much of the data frequencies are recorded as "near-field" data. In this situation the information with decreased transmitting frequency no longer becomes diagnostic of increasing penetration depth. The "near-field" notch generally occurs at 256Hz for the Beatrice survey data which is quite acceptable for Tasmanian conditions. Assuming an average overlying resistivity of 100 ohm.m, the effective penetration/investigation depth is computed to be approximately 500m.

Two of the main problems with CSAMT surveys for mineral exploration are in the removal of near-surface electrical in-homogeneity effects (known as statics) and the suitable modelling of data. Poor understanding of these problems has lead to the CSAMT technique often being either discounted as a viable exploration tool or being misinterpreted resulting in ineffectively positioned drill-holes. Processing and inversion techniques applied on the Beatrice data with the aim of addressing these problems are listed below:

- ZONGE TMA static correction
- EMAP algorithm static correction
- 1D inversion of data with and without static correction applied
- 2D inversion of data with and without static correction applied

The main conclusion drawn from the above processes was that no one technique provided the best section upon which a geological interpretation could be made. Each process had advantages and disadvantages.

Display of raw pseudo-section data was advantageous for observing near-surface (<200m) features whilst maintaining maximum lateral resolution. The main disadvantages are that the apparent resistivity values are not absolutely diagnostic of the resistivity of the detected anomaly and depths to features are not quantified. Statics correction of raw data displayed as pseudo-sections are useful for viewing deeper resistivity features through removal of statics effects. Statics effects are introduced through the low frequency component of shallow resistivity features. These often mask the lower frequency response caused by deeper features and must be removed. The TMA technique operates as an averaging filter and has the apparent disadvantage of removal of near-surface narrow wavelength features and also the in-complete removal of statics effects. The EMAP algorithm for statics correction may be regarded as a more robust algorithm physically, however analysis of raw data from the Beatrice examples would suggest the removal of some that are quite apparently real features (possibly due to edge effects of the filter algorithm).

1D inversion of data without first applying statics corrections produced depth-resistivity sections that exhibited quite severe statics effects. Statics removal using the TMA and EMAP algorithms were both found to be effective. The EMAP algorithm shows clear evidence for less statics induced anomalies at depth than those using the TMA filter. 2D inversion of data provides a very smoothly varying depth section that is perhaps not too well represented by the geology. Statics effects are not observed in the 2D inversion results. This is most likely a consequence of the smoothness of the resultant model.

Comparison of pole-dipole induced polarisation (IP) data acquired over the same two lines at the Beatrice Prospect show that the IP data were far more effective in detailed mapping in the 0-300m depth interval. The CSAMT technique seems more suited to mapping bulk resistivity variations and was unable to delineate discrete shale horizons at

shallow depths (0-300m) unlike the IP technique which proved very effective in this task. Analysis of raw pseudo-sections and inversion results showed that the CSAMT data suffered significantly from statics caused by the variably conductive gently folded Itac Creek Shale horizon. The main advantages of the CSAMT technique were not able to be highlighted by acquisition of two survey lines at the Beatrice Prospect. The main advantages are the ability to map down to 1000m (if a significantly large enough system existed at that depth). This ability to delineate targets down to 1000m relies on the absence of significant statics effects. Subtle geological features (eg moderate to low resistivity shales) are not able to be detected to this depth. Statics are usually caused by a variable overburden. At Beatrice the variably thick black shale horizon provided the geological unit causing statics effects. Mapping effectively to 1000m would require a generally resistive host geological sequence. The CSAMT technique would require a very significant conductor to provide anomalous response within a zone of generally high background response. The absence of a quality conductor in the CSAMT results from the two lines acquired at Beatrice is a function of the geology and is by no means a fault of the technique but rather a reflection of the geological conditions. The analysis of variations in the resistivity structure from line to line provide the best means for interpretation of CSAMT sections. Quantification of the host response from line to line enables identification of anomalous responses. At Beatrice, the acquisition of only two lines did not provide the means for a detailed interpretation.

Recommendations are outlined as follows:

- CSAMT is applicable in the Central Volcanic Complex of Tasmania for reasons of ease of survey data acquisition and a requirement for a depth of investigation beyond 300m.
- There is no definitive interpretation procedure that should be followed to enable removal of statics effects from data. The EMAP algorithm is the most effective of the two techniques applied, however, the statics removal was not complete and a clear understanding of what comprises a static is required when interpreting data.
- 2D inversion of CSAMT data is apparently not at stage whereby it can adequately be used to model geological boundaries. The 2D inversion of the Beatrice data produced very smooth models that were not representative of known 2D geology. This may have simply been a consequence of smoothing parameters chosen for the inversion process. As the inversion was conducted by contractors using software not available to Pasminco, there was no control able to be placed into the 2D inversion process. Experience with the ZONGE IP inversion software has shown that default smoothing parameters can be inadequate for mapping sharp 2D geological boundaries in the Beatrice region. It could also be the fact that the sample acquisition frequencies are not close enough to allow resolution of features. It is recommended that acquisition of addition frequency data be investigated.
- IP inversion results were quite clearly superior for the purpose of resolving electro-geological boundaries in the 0-300m depth interval. Application of the IP must be considered as the technique of choice for analysing the 0-300m depth interval at prospects where the geology is similar to that observed at Beatrice.

2. INTRODUCTION

The Beatrice Prospect is situated within EL6/98 approximately 7 km's north of the town of Queenstown in Western Tasmania (Figure 1.). The ground is currently being explored by Pasminco Exploration for its potential to host Rosebery style Zn-Pb-Ag-Au mineralisation within Palaeozoic volcanics and volcaniclastic sediments of the Central Mt Read Volcanics. The region also has potential for Mt Lyell style Cu-Au mineralisation. This report presents results of a controlled source audio magneto-telluric (CSAMT) survey conducted by Zonge Engineering Pty Ltd (Zonge) for Pasminco Exploration during April 1999.

The CSAMT technique is a deep sensing (effectively up to 1000m) electromagnetic geophysical method that produces anomalous response over geological units that have low electrical resistivity (or conversely high conductivity). The technique has application in the Central Volcanic Complex of Western Tasmania in the delineation of discrete conductive zones that may be associated with electrically connected conductive sulphide accumulations within economic Zn-Pb-Cu-Ag-Au deposits. The technique may also assist with delineation of more subtle conductive zones that could be associated with large alteration systems.

One of the aims of the CSAMT survey at Beatrice was to act as a technique evaluation study. Only two lines of data were acquired (800N and 2000N). These data are coincident with drilling information and pole-dipole IP data to allow comparison of results. Ideally it would have been advantageous to acquire additional lines of CSAMT for a detailed comparison, however, budgetary constraints could not permit such a programme. Various processing techniques were applied on the dataset to allow an evaluation of optimum processing parameters to be applied on CSAMT data. It was also intended that the CSAMT data may assist with the interpretation of the IP data on these two lines and possibly delineate anomalous response that could provide focus for drill testing.

3. LOCAL GEOLOGY AND PREVIOUS WORK

This geological summary is extracted directly from a report on pole-dipole results acquired at the Beatrice Prospect, Dauth (1999). The geology is derived predominantly from general discussions and field observations with project geologists.

The Beatrice Prospect comprises a prospective horizon of the Cambrian Mt Read Volcanics at the top of the Central Volcanic Complex (CVC). The CVC comprises predominantly felsic volcanics and volcaniclastics and is typically overlain by a sequence of shales, siltstones and sandstones. It is conceptual that this contact provides a focus for mineralisation either by acting as a fluid trap and favourable geochemical site via the overlying shales, or as the sea-floor position for Koroko style VHMS mineralisation deposited during a period of quiescence. A quartz-feldspar porphyry has intruded possibly as a sill along this contact and is a prominent feature of the local geology (the Mt Sedgewick Porphyry). The Ordovician Owen Conglomerate forms topographic ridges and scree slopes that abut onto the prospective ground. Remnants of eroded Permian sediments as horizontal layered clay/silt/sand beds are also evident in the region.

The simplified local geology comprises a gently folded to steeply dipping north-south striking black shale horizon situated at the contact between overlying porphyry and underlying volcaniclastic and felsic volcanic units. The black shale outcrops along a fault expressed along a present day drainage (Itac Creek) and is interpreted to dip steeply to the west and then gently fold to form an anticline in the west underlying the Mt Sedgewick Porphyry. Minor Pb-Zn mineralisation is observed in outcrop and in drill intersections within the black shale and underlying siliclastics. The two areas with potential for further mineralisation are considered to be the steeply dipping shale in the Itac Creek and the extensions of this shale (and ashes-shales-ignimbrites) that underlie the Mt Sedgewick Porphyry to the West and East of Itac Creek.Exploration to date has focused upon the black shale units that are situated strike parallel with the Itac Creek Fault.

Previous work has been summarised by Denwer (1998) in an unpublished report for Pasminco Exploration. Initial work at the prospect commenced in 1975 with stream sediment sampling and geological mapping. Subsequent work included:

- Establishment of over 40 km's of gridding - 1976-present
- 38 line km's of gradient array IP surveying - 1976
- Additional soil sampling - 1977-78
- Drilling MS1, MS2, and MS3 - 1978
- EIP, DHIP, dipole-dipole, and pole-dipole IP geophysical surveys (SCINTREX) - 1978
- Drilling MS4, and MS5 - 1979
- Ground magnetics, gradient array IP, pole-dipole IP, dipole-dipole IP - 1979
- Fixed loop UTEM - 1989
- Drilling MS06 - 1996
- MMI geochemistry - 1998-99
- Drilling MS07-MS09 and pole-dipole IP- 1998-99

4. SURVEY SPECIFICATIONS

The survey specifications are tabulated below:

Date of Survey:	April 1999
Contractor:	ZONGE Engineering Pty Ltd
Survey Type:	CSAMT
Approx. Line km's:	4 km
Line Spacing:	1200 m
Configuration:	H polarisation
H Field Spacing:	200m
E Field Spacing:	50 m
Receiver:	GDP32
Frequency Range:	8192, 4096, 2048, 1024, 512, 256, 128, 64, 32 Hz
Transmitter:	Zonge 30KW
Transmitter Length:	1.5 km
Transmitter Location:	Approximately 8 km's south of the survey region (-8150mN local grid).
Contract Number:	PASEXP023

Porcelain pots filled with $CuSO_4$ saturated solution were used for E-field receiver dipole electrodes. Aluminium foil lined pits were used as transmitter electrodes at the transmitter electrode positions. Two wire lengths were placed between the transmitter electrode pits to allow lower resistance (particularly required at the higher frequencies). The location of the transmitter electrodes is provided below:

AMGEast	AMGNorth	Local East	Local North	RL_mAHD
381772	5338689	943.87	-8092.65	360
380703	5339219	-245.68	-8208.72	275

A location diagram defining the transmitter position with respect to the survey area is shown in Figure 1. The transmitter wire was oriented parallel with the survey lines. Measurements were made of the electrical field parallel to survey line direction and magnetic field perpendicular to the line direction. This is referred to as E_XH_Y data or the transverse magnetic mode (TM).

Four E-field receiver dipoles were read simultaneously for each H-field measurement. The method of data noise and repeatability control was as follows:

- Two readings are taken at each station.
- If the readings lie within 5% error then an average of the two is taken as the result.
- If the readings lie outside of 5% error, then a third reading is taken. If the error lies within 10%, then an average is taken as the result.
- If the three readings lie outside of 10% error, then a fourth reading is taken. If the error lies within of 15% then the average is taken as the result.

- Five readings is specified as a maximum amount to be recorded taking the average values as final data.

A total of 4 line km's of data were acquired on two separate lines (800N and 2000N). The location of the Beatrice Grid is displayed in the location plan of Figure 1. A total of 5 days were required to acquire the 4 line kilometres (1.5 days of which were setting up and packing away the transmitter), equating to 0.8 km's per day and costing approximately $AUS2000/km.

5. TECHNICAL CONSIDERATIONS

CSAMT is an electromagnetic geophysical method that provides information on the ground electrical properties by mapping both lateral and vertical contrasts in resistivity. The method is commonly used to map sub-surface resistivity variations to depths in-excess of 2km. It has been the experience of the author of this report that the effective depth of exploration with the technique in Western Tasmania is in the order of 1km (this takes into account such factors as the geology, noise envelope, logistical constraints, and the types of targets being sought).

An artificially induced electromagnetic field is produced by a 1-2km long grounded wire bipole powered by a high output transmitter and generator (the ZONGE system uses a 30KVA power source). The transmitter bipole is usually located 3-10km from the survey region in order to provide a uniform plane wave polarised electromagnetic field in the survey region throughout a range of applied frequencies across the transmitter (the frequency range usually applied for mineral exploration is in the range of 0.5 Hz to 32 kHz). A square-wave electric current is injected through the transmitter at each of these frequencies for each measurement point. The frequency of the signal is varied in order to vary the depth of penetration (the lower the frequency the deeper the penetration). The orientation of the transmitter may be perpendicular (E-polarisation) or parallel (H-polarisation) with the survey line direction (where the survey line direction is typically the direction perpendicular to geological strike). The H-polarisation mode is used for the Beatrice survey. Results presented by Kellet et al (1993) describe the E-polarisation method being more effective for delineation of tabular bodies due to the dominance of current gathering effects. Disadvantages of the E-polarisation (and reasons for not using the configuration) are that current gathering may be induced in lithologies lying between the survey area and the transmitter and thus act as a shield to the area of interest. A more significant disadvantage in rugged and densely vegetated terrain (such as Beatrice) is that measurements of the E-field are required to be made perpendicular to the line direction for E-polarisation surveys. This would be extremely costly logistically in the Western Tasmania region.

Measurements were made of the horizontal electrical field (E_x) and magnetic field (H_y) components of the electromagnetic field at the frequency of the applied field at the transmitter. A separate measurement of the phase shift between the E-field and the H-field is also measured. These measurements are used to yield the following diagnostic parameters:

Cagniard Resistivity = $(1/5f) \times |E_x/H_y|^2$ units of ohm.m

Impedance Phase = E Phase - H Phase units of milliradians

These parameters are functions of the ground resistivity, survey configuration and depth. The depth of investigation with the CSAMT technique is a function of the ground resistivity and the frequency of the transmitted electromagnetic field. The lower the frequency the greater the depth of investigation. In electromagnetic surveying the "skin

depth" equation is often used to describe the distance at which the signal is reduced by $1/e$, that is, to 37%.

$$\text{Skin depth} = 500 \times (\text{resistivity/frequency})^{1/2} \text{ (Telford 1991)}$$

It can be shown (Asten 1999) that this equation can be used to derive an "equivalent depth of investigation, D" for the CSAMT technique as:

$$D = 356 \times (\text{resistivity/frequency})^{1/2}$$

Therefore, assuming a lower frequency of 64 Hz and a host resistivity of 2000 ohm.m (quite realistic for the volcanic terrain of the Central Mt Read Volcanics), the depth of investigation may be up to 2km. In order to resolve an anomalous signature we would hope to observe at least three frequencies within the anomaly, hence an effective depth of investigation is better described using 256 Hz, providing effective depth of investigation of 1km. Where the host horizon is more conductive (presence of shales) then this depth may be as shallow as 500m or even less. It should be pointed out that the resistivity used in the "D" equation is the bulk resistivity. Therefore if a highly conductive unit (low resistivity) unit overlies a resistive unit then it is possible that the lower unit may be masked by the overlying conductive unit.

Data are typically plotted as pseudo-sections whereby the Cagniard Resistivity is plotted against the measurement frequency. A feature of many plotted CSAMT pseudo-sections is an appearance of striped vertical anomalies on a background showing a layered appearance of increasing resistivity in the lower frequencies. The vertical anomalies are described as statics effects, and the horizontal layering are near-field effects. These are significant problems in CSAMT survey data and need to be understood to avoid mis-interpretation of data.

Statics

The vertical anomalies extending through many frequencies are often referred to as statics effects and are due to the fact that near surface conductivity features will also have a low frequency component (which can often dominate the amplitude of the low frequency component sourced from deeper conductive sources). Statics anomalies in lower frequencies can be discriminated from actual deep sourced anomalies by the fact that physics demands that the wavelength of anomalies increases with depth of the source. Anomalies caused by statics will not increase in wavelength with frequency since the source of the anomaly is still shallow sourced. A deep conductive source must provide a broad wavelength anomaly.

Two algorithms used to static correct the Beatrice CSAMT data are summarised as follows:

(Information provided by ZONGE Pty Ltd)

The trimmed-moving-average-filter (TMA) estimates near-surface resistivities by averaging apparent resistivities along line at a selected reference frequency (4096Hz). The highest frequency with "clean" data is typically used as the reference frequency. The method then computes the sounding curves that would arise from such a near surface resistivity and uses this to correct the data. The filter is described in more detail in APPENDIX 1.

The electromagnetic array profiling (EMAP) statics correction algorithm is described as a data-adaptive spatial filtering technique that responds to changes in local average resistivity at a given frequency to estimate both effective depth of response and resistivity along a survey path (Torres-Verdin 1992). Essentially the filtering applied on the data is dependent on both the resistivity and the frequency and arguably is more thorough in removal of statics due to the adaptive nature of the filter.

"Near-field effects"

In a CSAMT survey the distance between the transmitter and receiver lines is constrained by the following requirements

- That the distance be close enough that signal to noise characteristics of the data are satisfactory.
- That the distance is large enough that plane-wave assumptions are still valid.

Near the transmitter the field strengths (and hence S:N) is greatest however the plane-wave electromagnetic field assumption is no longer true. At a distance from the transmitter where the electromagnetic field becomes a plane-wave the recorded data is known as "far-field" and is suitable for modelling. The "far-field" distance is approximated by:

$$LF > 3 \times \text{Skin depth}$$
$$\text{where Skin depth} = 500 \times (\text{resistivity/frequency})^{1/2}$$

In the "near-field" zone the Cagniard Apparent resistivity formula over-estimates the actual apparent resistivity and the computed resistivity becomes a function of the transmitter frequency rather than the ground resistivity. "Near-field" data are not suitable for modelling, and when displayed in pseudo-section appear as horizontal lines due to the dependence on frequency rather than geology.

6. PROCESSING AND MODELLING PARAMETERS

A number of processing and inversion techniques were applied on the Beatrice data with the aim of determining the advantages and disadvantages of the different algorithms. Those trialed are listed below:

- ZONGE TMA static correction
- EMAP algorithm static correction
- 1D inversion of data with and without static correction applied
- 2D inversion of data with and without static correction applied
- Bostick inversion

Zonge Engineering Pty Ltd conducted the TMA static correction and all 1D and 2D inversion. 1D and 2D inversion were conducted with Zonge developed software. Michael Asten of Flagstaff Geoconsultants conducted the EMAP statics correction of data.

The 4096 Hz data were used for the TMA statics correction filter. Default model smoothing parameters were used for 1D and 2D modelling. The budget of the project did not allow for modelling tests trialing different model smoothing parameters.

Model parameters for the 1D inversion are outlined below:

```
&SCSINV
Header(1)='From SCSINV v1.22h  Date:14/04/99  Time:13:53:09'
Header(2)='BEATRICE PROSPECT  Line 800 N'

```

The following information on CSAMT smooth model inversion was provided by Zonge Engineering Pty Ltd.

" Smooth model inversion is a robust method for converting CSAMT measurements to models of resistivity versus depth. Observed apparent resistivity and impedance phase data for each station are used to determine the parameters of a layered earth model. Layer thickness are fixed before the inversion starts by calculating source field penetration depths for each frequency. Layer resistivities are given a uniform starting value based on controlled source apparent resistivities. Layer resistivities are adjusted iteratively during inversion until the calculated CSAMT response is as close as possible to observed data, consistent with smoothness constraints. Including smoothness constraints in the inversion limits resistivity variation from layer to layer and produces a model with smoothly varying resistivities. SCSINV, Zonges forward modelling algorithm can include the effects of finite transmitter-receiver separation and a three dimensional source field. Therefore depth of inversion is limited as only "far-field" data can be inverted. Source types include a vertically incident plane wave for natural source modelling and grounded electric bipole or horizontal loop sources for CSAMT modeling. Accurate impedance magnitude and phase values are calculated for all frequencies and transmitter-receiver separations. Impedances can be calculated for scalar, vector, or tensor survey configurations. Lateral variation is determined by inverting successive stations along a survey line to produce a grid of smooth model resistivity. Resistivity values are placed at the midpoint of each layer, forming a column below each station. The columns form an array representing a cross-section of model resistivity. Results from a complete line can be represented in pseudo-section form by contouring model resistivities. Inverting apparent resistivity and impedance phase to smoothly varying model resistivities is an effective way to display the information inherent in CSAMT measurements. Smooth model inversion does not require any prior estimates of model parameters. The data are automatically transformed to resistivity as a function of depth. Models with smoothness constraints are complementary to more detailed models incorporating specific geologic information. "

7. DISCUSSION AND RESULTS

Data are provided as pseudo-sections of Cagniard Resistivity (raw and static corrected), E-field, H-field, phase, and statistical error in Plan 1 and Plan 2 for Line 800N, and 2000N respectively. Pseudo-sections of pole-dipole IP data are also provided in Plan 1 and Plan 2 to allow comparison between data from different techniques. Common colour histogram stretches and contour intervals have been applied to the resistivity data to allow comparison of the statics correction algorithms.

Data Interrogation (it is recommended that Plan 1 and Plan 2 be viewed whilst reading this section)

The TMA static corrected data clearly show evidence that statics effects remain in the data. The EMAP static corrected data do not show evidence of statics remaining in the data. Thus is could be inferred that the EMAP process performed a more thorough removal of statics effects. Both statics correction algorithms result in removal of high frequency features. Discrete anomalies detected at 8192Hz (eg those observed in Line 800 over one dipole at -675E, -525E, and -275E) have been removed in both statics corrected sections. It has been the experience of the author of this report that many of these features are commonly narrow geological units outcropping or just below the surface. The CSAMT can provide good geological information on these units, and statics correction has the undesirable effect of removal of these high frequency features.

Near-field data are encountered at and below 256Hz across most of the survey line. The equivalent depth of investigation at 256Hz assuming an average overlying resistivity of 1000 ohm.m is computed using:

$$D = 356 \times (\text{resistivity}/\text{frequency})^{1/2}$$

such that D = 700m.

Therefore it is assumed that we are investigating approximately 700m with the CSAMT data. The low resistivity layer observed on both lines at 256Hz (most apparent in the EMAP static corrected section) cannot be explained geologically. The impedance phase section clearly shows that the transition to the near-field occurs at 256Hz. This transition is represented by a sharp increase in the Hy field. The sharp increase in the Ex field data is not evident until 128Hz. Therefore since the computed resistivity is proportional to Ex/Hy, the increase in the Hy field at the transition to near-field data explains the low resistivity feature observed at 256Hz. Therefore, only data at frequencies of 512Hz and higher should be given full validity as far-field data. Using 512 Hz in the "equivalent depth" formula yields a depth of investigation of 500m.

The noise sections were able to be produced since more than one reading was taken at every station. Both Hy and Ex data show anomalous noise points. Typically the greatest noise is exhibited at 256Hz. Ex noise is an order of magnitude worse than the Hy noise. The Hy noise does not appear to introduce anomalous response whereas the Ex field noise does (eg -525E at 128-256 Hz and -1525E at 128-256 Hz in Line 800N). Noise

between Ex and Hy cannot be correlated and are observed to occur at different locations and often at different frequency. Three possible causes are postulated, however neither can be proven without further work:

1. The noise is a consequence of instability at the near-field to far-field transition.
2. The noise is due to powerline interference at 50Hz (256Hz is a multiple).
3. the noise was introduced through field procedure or intermittently faulty equipment.

Electromagnetic noise is more severe in data collected on Line 800 than for Line 2000. Data were collected on different days, hence differing atmospheric conditions or slightly different geological conditions may explain the difference in errors. It is perhaps equally likely that the errors could be explained by equipment problems. Noise observed in the Ex field data seem to be most apparent in the impedance phase parameter. The two main anomalous responses in Line 2000N for the phase parameter are at -625E and -1225E at 256 Hz where anomalous noise is recorded for the Ex field data. Noise is not considered a prohibitive problem for the Beatrice survey data but definitely must be taken into account due to the fact that several anomalous responses are apparently due to noise.

Modelling Results

Results of 1D and 2D inversion processes are presented in Plan 3 and Plan 4 for Line 800N and Line 2000N respectively. Resistivity inversion results from pole-dipole IP data have been placed on Plan 3 and Plan 4 to allow comparison between techniques. Modelling results are discussed independently for each line below (it is recommended that the corresponding Plan is viewed whilst reading this section):

LINE 800N (Plan 3)

Inversion results from Line 800N CSAMT data do not significantly change when comparing the 1D inversion with and without the TMA static correction. Application of the EMAP statics correction to the 1D inversion and 2D inversion result in removal of the depth extent of low resistivity anomalies centred on -900E, -1500E, and -1700E. The depth extent of these anomalies depicted in the 1D inversion of the TMA and non-static corrected data are considered to be statics effects and not representative of geology. Several anomalous zones are detected in the data that are thought to be generated by the near to far field transition zone (and the low resistivity layer it causes at 256Hz discussed in the previous section). Anomalies considered to be non-geological and caused by this transition effect are centred on; -1050E, 200mRl; -1375E, 200mRL; and the broad zone on the western end of the line below 400mRL. Originally these may have been thought as prospective deep targets, however closer interrogation of the data determines them to be data acquisition effects.

There appears to be little difference between the 2D inversion section with and without the EMAP statics correction. This is perhaps due to the extremely smooth nature off the 2D inversion. Since statics effects can be removed through smoothing of the section data it is thought that the 2D inversion process effectively achieves this filtering task. This

possibility has not been further tested. The anomalously low resistivity values in the 2D inversion sections at -1000E below 200mRL are interpreted to be edge type effects ("rising sun" effects), and are not considered as trult diagnostic of the geology. It is most likely that variation of these resistivity values would not have significant impact on the validity of the model.

The IP resistivity inversion section (data described in detail by Dauth 1999) quite closely match the CSAMT section data. The CSAMT data would require a very low resistivity layer or large volume low resistivity feature at depth to allow delineation in the data. The fact that the CSAMT data do not exhibit anomalous responses at depth provides information that such a large conductive system is unlikely to be present. Resolution of the Itac Creek Shale horizon at depth has not been achieved with the CSAMT data. This is interpreted to be due to the fact that this horizon does have a large enough volume and low enough resistivity to allow resolution.

LINE 2000N (Plan 4)

Inversion data from Line 2000N closely match the results from Line 800N. 1D inversion using the non-static and TMA static corrected data show evidence of statics induced responses in the depth sections that are not evident in the 1D EMAP and 2D inversion sections. Again the 2D inversion results do not appear to show much difference whether the EMAP statics correction has been applied or not.

An interesting feature of the data is to notice the difference in resolution between the 2D resistivity inversion of IP data and the CSAMT data. The galvanic resistivity data from the IP survey provided a far better resolution of geological boundaries by defining a folded low resistivity layer that is known to represent the Itac Creek Shale horizon. This horizon is represented in the CSAMT data by a very broad low resistivity zone. The IP data were inverted using smoothing parameters that allowed for a more rapid change in resistivity with depth than the CSAMT inversion parameters, hence the comparison is not entirely applicable. It is however thought that the resolving power of the IP data would be superior to the CSAMT given a greater density sample interval within the top 300m of investigation.

Data and inversion results from neither of the two lines provide a high priority drill target for Pb-Zn exploration on the Beatrice Prospect. Secondary targets are provided at the Itac Creek Fault position where black shales are observed in outcrop at -800E on Line 800N and where the shale unit extends close to the surface on Line 2000N at -1400E. Both are shallow (<200m) and are not recommended as drill targets in their own right without support from other exploration methods.

8. RECOMMENDATIONS

Recommendations are outlined as follows:

- CSAMT is applicable in the Central Volcanic Complex of Tasmania for reasons of ease of survey data acquisition and a requirement for a depth of investigation beyond 300m. The cost per km for the CSAMT was $2000 which compared quite favourably to the IP survey cost of $7000/km. However it should be kept in mind that alternative field procedures are being considered for IP surveying that will make it more cost effective. In addition, the proposal to acquire addition frequency content in the CSAMT data would make CSAMT comparable in price with a modified field practice IP survey. IP data have an advantage of acquisition of the polarisation parameter in addition to resistivity.
- There is no definitive interpretation procedure that should be followed to enable removal of statics effects from data. The EMAP algorithm is the most effective of the two techniques applied, however, the statics removal was not complete and a clear understanding of what comprises a static is required when interpreting data.
- 2D inversion of CSAMT data is apparently not at stage whereby it can adequately be used to model geological boundaries. The 2D inversion of the Beatrice data produced very smooth models that were not representative of known 2D geology. This may have simply been a consequence of smoothing parameters chosen for the inversion process. As the inversion was conducted by contractors using software not available to Pasminco, there was no control able to be placed into the 2D inversion process. Experience with the ZONGE IP inversion software has shown that default smoothing parameters can be inadequate for mapping sharp 2D geological boundaries in the Beatrice region. It could also be the fact that the sample acquisition frequencies are not close enough to allow resolution of features. It is recommended that acquisition of addition frequency data be investigated.
- IP inversion results were quite clearly superior for the purpose of resolving electro-geological boundaries in the 0-300m depth interval. Application of the IP must be considered as the technique of choice for analysing the 0-300m depth interval at prospects where the geology is similar to that observed at Beatrice.
- Noise analysis is a very important component of CSAMT data interpretation. E field and H field noise characteristics should be plotted independently to determine the nature of the noise component.
- In future noise analysis should be conducted prior to inversion of data and points considered to be noisy or to exist at the near-field transition should be omitted from the process.
- No direct drill targets have been recommended as a result of the CSAMT results alone.

1. SUMMARY

During August 1999 down-hole electromagnetic data (DHEM) using the CRONE PEM system were acquired on diamond drill-holes MS07 and MS09 at the Beatrice Prospect. The Beatrice Prospect is situated in Western Tasmania within EL 6/98 approximately 7 kilometres north of the town of Queenstown. Outer-Rim Exploration Services were commissioned to complete the DHEM survey for Pasminco Exploration who are currently exploring the ground for Rosebery style Zn-Pb-Ag-Au mineralisation. Data were acquired using the CRONE DHEM time domain electromagnetic system.

The aim of the DHEM survey was to delineate anomalous EM response that could be attributed to massive sulphide mineralisation for the purpose of defining further drill targets in the vicinity of either drill-hole MS07 and/or MS09. It is estimated that the DHEM technique would effectively explore within a 200 metre radius of the current drill-hole position. It must be considered that when reviewing this SUMMARY, and when applying the DHEM technique, that economic sulphide mineralisation may not necessarily provide a recognisable response (eg Hercules, Western Tasmania), and that some geological conditions provide anomalous EM response that is not associated with economic sulphide mineralisation (eg graphitic/pyritic black shales).

DHEM data were acquired in the time-domain using an impulse response (square-wave signal) CRONE PEM system. Data were acquired on 18 separate channels (including the "Primary Field" or PP measurement) on a 10 msec timebase. Three-component data were collected at 10 m intervals for the entire length of the 550m and 387 m drill-holes (MS07 and MS09 respectively). Two transmitter loops were used for logging MS07 to allow for variations in coupling of a conceptual sub-surface conductor. Unfortunately only one transmitter loop was used for logging MS09 for logistical reasons. The survey required helicopter support and impending poor weather conditions only allowed one days surveying on the hole. Rather than collect axial data using two different transmitter loop positions it was decided to acquire cross-component data using the one transmitter loop (this was based upon results from logging MS08 which indicated that the cross-component data were arguably more useful than the axial component).

DHEM data acquired on a nearby drillhole (MS08) in April had delineated a subtle off hole response (previously reported). The report on the interpretation of DHEM data from MS08 recommended logging of MS07 and MS09 to determine whether the response detected in MS08 could be confirmed or disregarded as having potential for being sourced from economic sulphide mineralisation. Off-hole responses were detected in MS07 and MS09. The modelled location of the source of off-hole responses depended on the hole geometry and loop configuration and was unable to be suitably constrained by modelling. Nonetheless it is interpreted that the responses are formational (due to black shales and/or a pepperitic unit at the black shale/porphyry contact). This interpretation is based upon drilling results from MS09, physical property measurements on MS05, MS08 and MS09, induced polarisation data, and reference to geological sections. No drill targets were recommended based upon the DHEM results.

2. INTRODUCTION

The Beatrice Prospect is situated within EL6/98 approximately 7 km's north of the town of Queenstown in Western Tasmania (Figure 1). The ground is currently being explored by Pasminco Exploration for its potential to host Rosebery style Zn-Pb-Ag-Au mineralisation within Palaeozoic volcanics and volcaniclastic sediments of the Central Mt Read Volcanics. The region also has potential for Mt Lyell style Cu-Au mineralisation.

This report presents results of a down-hole electromagnetic (DHEM) survey on diamond drill-holes MS07 and MS09 conducted by Outer Rim Exploration Services for Pasminco Exploration during August 1999. The aim of the DHEM survey was to delineate anomalous conductivity response that would be directly associated with massive sulphide mineralisation, and thus provide a target for further exploratory drilling. Previous DHEM logging conducted on a nearby drillhole (MS08) in April 1999 detected anomalous off-hole EM response. It was intended that results from MS07 and MS09 would assist with interpretation of the source of the response detected in MS08. If the response was confirmed (and shown to be discrete in location) then drill testing would be recommended.

3. LOCAL GEOLOGY AND PREVIOUS WORK

This summary of the geology and previous work is taken from the previous report on DHEM results on MS08 (Dauth 1999).

The Beatrice Prospect comprises a prospective horizon of the Cambrian Mt Read Volcanics at the top of the Central Volcanic Complex (CVC). The CVC comprises predominantly felsic volcanics and volcaniclastics and is typically overlain by a sequence of shales, siltstones, and sandstones (interpreted to be Lower Tyndall Group). It is conceptual that this contact provides a focus for mineralisation either by acting as a fluid trap and favourable geochemical position via the overlying shales, or as the sea-floor position for Koroko style VHMS mineralisation deposited during a period of quiescence. A quartz-feldspar porphyry has intruded possibly as a sill along this contact and is a prominent feature of the local geology (the Mt Sedgewick Porphyry). The Ordovician Owen Conglomerate forms topographic ridges and scree slopes that abut onto the prospective ground. Remnants of eroded Permian sediments as horizontal layered clay/silt/sand beds are also evident in the region.

The simplified local geology comprises a gently folded to steeply dipping north-south striking black shale horizon situated at the contact between overlying porphyry and underlying volcaniclastic and felsic volcanic units. Locally the black shale is intercalated with both the overlying porphyry and the underlying ashy volcanics. The black shale outcrops along a fault expressed as a present day drainage (Itac Creek) and is interpreted to dip steeply to the west and then gently fold to form an anticline in the west underlying the Mt Sedgewick Porphyry. Minor Pb-Zn mineralisation is observed in outcrop and in drill intersections within the black shale and underlying siliclastics. The two areas with potential for further mineralisation are considered to be the steeply dipping shale in the Itac Creek and the extensions of this shale (and ashes-shales-ignimbrites) that underlie the Mt Sedgewick Porphyry to the West and East of Itac Creek.

Exploration to date has focused upon the black shale units that are situated strike parallel with the Itac Creek Fault.

Previous work has been summarised by Denwer (1998) in an unpublished report for Pasminco Exploration. This work is further summarised into point form as follows:

- Stream sediment sampling and geological mapping - 1975
- Establishment of over 40 km's of gridding - 1976-present
- 38 line km's of gradient array IP surveying - 1976
- Additional soil sampling - 1977-78
- Drilling MS1, MS2, and MS3 - 1978
- EIP, DHIP, dipole-dipole, and pole-dipole IP geophysical surveys (SCINTREX) - 1978
- Drilling MS4, and MS5 - 1979
- Ground magnetics, gradient array IP, pole-dipole IP, dipole-dipole IP - 1979
- Fixed loop UTEM - 1989
- Drilling MS06 - 1996
- Drilling and DHEM logging; MS07, MS08, and MS09 - 1998-99

Drillhole MS07 was drilled to 550 m to test two targets (taken from the Pasminco December 1998 monthly report):

1. To test the hypothesis that the mineralisation stratigraphy at Itac Creek of black shale underlain by course volcaniclastics underlain by fine ashy volcaniclastics was repeated below the quartz-feldspar porphyry.
2. At the Itac Creek the mineralised stratigraphy dips into the Itac Creek Fault. Unless this stratigraphy is dragged into the fault then there is no depth potential at Itac Creek. MS07 is planned to drill through the Itac Creek Fault to ascertain if the stratigraphy is rotated into the fault.

Results suggested that there is significant depth potential at Beatrice. A summary log follows:

0-109m Quartz feldspar porphyry
109-232m Black shale
232-254m Quartz feldspar porphyry
254-258m Black shale
258-261m Quartz feldspar porphyry
261-417m Coarse pumiceous volcaniclastic massflows
417-550 Ashy volcaniclastic, minor massflow units

Drill-hole MS8 was completed at 798.7m and targeted at a geochemical anomaly on the prospective Itac Creek stratigraphy beneath the Mt Sedgewick quartz feldspar porphyry. A summary log from the drill-hole follows (taken from the Pasminco April 1999 Internal Monthly Report):

MS08 Summary Log:

From	To	
0.0	191.8	Quartz feldspar porphyry.
191.8	197.8	Volcaniclastic sandstone and shale.
197.8	292.9	Quartz feldspar porphyry.
292.9	306.2	Intercalated black shale and quartz feldspar porphyry
306.2	318.2	Black shale
318.2	344.2	Intercalated black shale and quartz feldspar porphyry (peperitic contacts)
344.2	373.7	Black shale and minor sandstone; major fault zones at 360.1-364m and 371.6-373.7m; Sphalerite-rich mineralisation in lower 2m of unit.
373.7	447.3	Quartz feldspar porphyry. Strongly Sil-Co-Chl±Kfs veined with weak sphalerite>galena minerlaisation.
447.3	583.3	Black shale and minor siltstone/sandstone. Sphalerite> galena Mineralisation from 557 - 583.3m.
583.3	651.6	Quartz feldspar porphyry
651.6	665.4	Ash volcaniclastic and minor volcaniclastic sandstone. Generally 0.5-1.0% sphalerite, but, up to 5% sphalerite in matrix of sandstone units.
665.4	696.5	Volcaniclastic sandstones (pumiceous) with trace sphalerite.

696.5	787.3	Intercalated shale and volcaniclastic ash to sandstone units. Variable Py±Sp>Gn mineralisation; narrow intervals of up to 10% Sp (in sandstone beds) but generally <0.5% Sp.
787.3	798.7	Volcaniclastic sandstone/breccia with Sil+ Kfs/hem alteration. Only trace Py+Cpy.

Drillhole MS09 was drilled to 387 m to test an anomalous chargeability zone detected in a pole-dipole survey reported by Dauth 1999. The hole intersected pepperitic porphyry/shale and underlying shale (explaining the IP anomalism). The shale in MS09 appears slightly more graphitic and pyritic than in previous drillholes. A summary log follows:

0-58m Pepperite
58-234m Black shale
234-387m Porphyry

Physical property measurements on several samples from MS07 indicate that the black shale does not provide an inductive conductivity that would be expected to provide an anomalous EM response. It must however be pointed out that the black shale is unlikely to be homogenous in electrical character and that several discrete measurements would not provide a suitable sample base to describe the electrical properties of the shale as a whole.

Measurements were taken on core samples of MS05, MS08, and MS09 using a simple ohm.meter. Two electrodes of rectangular metal (1.3 x 2.75 cm) were separated by 9 cm and connected to the uncut core using a solution of NaCl (approximately 10,000 mg/l). These measurements were designed to test the electrical properties of the core as a bulk sense (since single measurements are unlikely to be diagnostic of the entire rock volume). Resistances were measured at 1-4 m interval down the core and are plotted in Figure 3 to Figure 5. Results indicate that the pepperite unit overlying the black shale in MS09 is most likely the more conductive of all units intersected in any of the holes. The black shale in MS05 and underlying the pepperite in MS09 is also more conductive than the black shale unit intersected in MS08 (which returned more favourable mineralisation). This has important implications in the way we view the electrical data acquired at the Beatrice Prospect. These implications are summarised below:

1. The black shale varies in electrical properties and may in places provide anomalous electrical response.
2. The pepperite unit overlying the black shale may also produce anomalous electrical response in places.
3. Anomalous electrical geophysical response at the Beatrice Prospect are highly likely to be attributable to formational sources.

4. SURVEY SPECIFICATIONS

The survey conducted by Outer Rim Exploration Services using the CRONE PEM system.

The survey specifications are tabulated below:

Date of Survey:	August 1999
Contractor:	Outer Rim Exploration Services
Survey Type:	DHEM
System:	CRONE PEM
No. of Drillholes:	2 (MS07 and MS09)
Components:	Axial (A) and cross-components (U and V)
Station Spacing:	10m (A, U, and V)
Time Base:	10 msec
Channels:	18 including the PP field
Ramp Time:	500 μsec
Synchronisation:	Cable
Transmitter Size:	400m x 300m and 600m x 400m
Current:	7A and 20A Amps

The method of data noise and repeatability control was as follows:

- Two readings were taken at every station and compared for repeatability. Additional readings were taken as required.

Two transmitter loop positions were utilised for MS07 and one loop position for MS09. For reference within the text of this report these loops have been labelled BEM1, BEM3, and BEM4 (transmitter loop BEM2 was not utilised for this survey). The location of transmitter loops is presented in Figure 2. Transmitter loop corner coordinates (local and AMG) are provided below:

Loop	Corner	Local East	Local North	AMG East	AMG North	RL
BEM1	NW	-1700	2200	385020	5348712	990
BEM1	NE	-1350	2200	385310	5348546	1045

18	5.42900	1.52600

5. MODELLING PARAMETERS

Data were modelled using the FILAMENT modeling software invoked through the EMVISION EM modelling and visualisation package. The FILAMENT software is capable of inversion of results to provide minimum error between observed and modelled data, however computer inversion can have the undesirable outcome of producing non-geologically feasible results due to the non-uniqueness of solution. This is particularly the case whereby DHEM response is made complicated through superposition of response from multiple sources. It is for this reason that the software was used only in the forward modeling mode for modelling MS07 and MS09.

6. DISCUSSION AND RESULTS

Stacked profiles of the down-hole response are presented in the contractors report as APPENDIX I. Results from each drill-hole and loop are discussed separately and then summarised.

MS07

BEM 3

Axial data from BEM3 show anomalous EM response as a late-time (channel 7-12) broad low with sharp shoulders from 100 m to 320 m down-hole. Early time channels (1-7) show a positive response over this interval. Cross-component results similarly show anomalous response across this interval. This depth range corresponds with intersected black shale in the drill-hole and the response is interpreted to be formational. High amplitude response at the top of the hole is due to the fact the receiver is most likely overloading since the transmitter loop edge passes within 10 m of the hole collar. In addition a large steel platform (a loop of dimension 5 x 5 m used to transport the drill rig) was situated at the loop collar and would no doubt influence the DHEM response to about 100 m or so down-hole.

BEM 4

Transmitter loop BEM 4 was designed to couple with a vertical to steeply easterly dipping conductor within the Itac Creek Fault. Results are similar to those achieved using the BEM 3 transmitter (ie a response shoulder is detected at 320 m down-hole that provides evidence for a formational response and high amplitude responses detected at the top of the hole due to loop location and culture near the collar position). The cross-component data (X and Y in the APPENDIX I) show positive to negative crossover centred at 160 m down-hole in the X component and a broad positive Y component centred at approximately 260 m down-hole. An attempt was made to model this response. One suitable model was a ring current filament source centred at the following coordinates:

385150 mE
5347800 mN
460 mRL
Radius = 120 m
Azimuth = 70°
Dip = 68° to the east

This is very similar to MODEL 2 conductor described in Dauth 1999 as observed in DHEM data from MS08. This area is coincident with a low resistivity zone detected in historical gradient array IP data. The conductor position is coincident with a black shale position and is not considered a viable drill target on this basis. It must also be pointed out that this model is by no means a unique solution.

MS09

BEM 1

Drill-hole MS09 was logged using transmitter loop BEM 1. There are clearly long wavelength off-hole EM responses in the data centred at about 180 m down-hole. These are most likely to be formational responses (black shale/pepperite). Computer modelling was unable to provide a confident position for the location of the conductive source and it is thought that the actual geology is too complex for use of the simplistic EM models available with current software. More time could be spent to define the location of the conductive source however this would simply by an academic pursuit since the response is thought to be formational.

MODELLING RESULTS

Attempts to model the location of the conductive source causing the observed EM response have been at best ambiguous. It was very difficult to reconcile the differences in the three components for each hole and suitable simple geometrical models to explain the observed responses were not achieved. Consequently no profile results from modelling are presented within this report. It is currently thought that the complex folded geology comprising variably conductive black shale and pepperite has provided multiple sources for inductive and current gathering EM responses that are unable to be separated. Best estimates as to the location of conductive sources is possible and in all cases it appears that these locations correspond with black shale stratigraphy.

7. RECOMMENDATIONS

- No drill targets are recommended based upon the DHEM results from MS07 and MS09.
- The DHEM logging did confirm the presence of EM conductive responses as reported when MS08 was logged. These responses are currently thought to be formational.
- It has become apparent that the Beatrice area comprises geological units that give rise to anomalous EM response that could easily be targeted as a conductive sulphide body. Similarly it would also be possible to discount an EM response as formational when in fact the response could be due to sulphide mineralisation. Further DHEM logging at Beatrice is recommended on the basis that an orebody response could well be significantly more conductive than the observed formational responses and thus allow easy identification, however, it must be pointed out that the technique is by no means a sterilisation method since the EM response from a poorly conducting mineralised system (sphalerite rich) might be masked by the background response.

LIST OF PLANS

1. SUMMARY

During May 1999 down-hole electromagnetic data (DHEM) using the CRONE PEM system were acquired on diamond drill-hole MS08 at the Beatrice Prospect. The Beatrice Prospect is situated in Western Tasmania within EL 6/98 approximately 7 kilometres north of the town of Queenstown. Data were acquired by Outer-Rim Exploration Services using a PEM transmitter owned by Outer-Rim with the remainder of the DHEM system owned by Pasminco Exploration. Initial attempts to log the hole using the entire Pasminco system were abandoned due to a faulty PEM transmitter. Outer-Rim were then commissioned to complete the survey for Pasminco Exploration who are currently exploring the ground for Rosebery style Zn-Pb-Ag-Au mineralisation.

The aim of the DHEM survey was to delineate anomalous EM response that could be attributed to massive sulphide mineralisation for the purpose of defining further drill targets in the vicinity of drill-hole MS08. It is estimated that the DHEM technique would effectively explore within a 200 metre radius of the current drill-hole position. It must be considered that when reviewing this SUMMARY, and when applying the DHEM technique, that economic sulphide mineralisation may not necessarily provide a recognisable response (eg Hercules, Western Tasmania), and that some geological conditions provide anomalous EM response that is not associated with economic sulphide mineralisation (eg graphitic/pyritic black shales).

DHEM data were acquired in the time-domain using an impulse response (square-wave signal) CRONE PEM system. Data were acquired on 18 separate channels (including the "Primary Field" or PP measurement) on a 10 msec timebase. Three-component data were collected at 10 m and 20 m intervals for the entire length of the 798 m drill-hole. Axial component data were acquired at 10 m interval and cross-component data at 20 m interval. Two transmitter loops were used for the survey to allow for variations in coupling of a conceptual sub-surface conductor. Data are particularly noisy (not uncommon for Western Tasmania) and do not exhibit reasonable response past channel 12 (approximately 1.6 msec from cessation of the current ramp turn-off). A very interesting feature of the DHEM data is the lack of in-hole response coincident with intersections of the black shale units. This is encouraging in that it suggests the shales might not provide anomalous off-hole EM response as spurious anomalies. Given this information it must be considered that any off-hole response detected has a higher probability of being associated with sulphide mineralisation than the Itac Creek Shale (assuming homogeneity of the shale unit).

Data have been plotted using the ENCOM EMVISION software and modelled using the FILAMENT algorithm via a link through EMVISION. A subtle broad wavelength anomalous response was detected in the data from the transmitter loop to the east (BEM2) of the MS08 collar. The response is most apparent in the vertical cross-component (U) data, but also arguably evident in the axial (A) and horizontal cross-component (V). Modelling of the response using the FILAMENT algorithm suggests two possible source geometries.

1. A near-surface source striking N-S (grid) situated in the south-east corner of the

BEM2 loop dipping to the west. This position is coincident with the Itac Creek Fault and the Itac Creek Shale. The inverted ring filament providing a suitable fit between modelled and observed data has a radius in-excess of 100m and dips to the west with an eastern margin defined by the Itac Creek Fault. The fact that the transmitter loop side lies directly over the position of the Itac Creek Fault and adjacent Itac Creek Shales may have had the consequence of the high amplitude energising field near the loop causing local currents to be induced in the shale/and or fault. A current channelling response would have induced opposite polarity response to that detected hence it is inferred that the response must be inductive.

2. A source striking grid N-S situated off-section and parallel to the drill-hole MS08. An east dipping ring filament with a radius of approximately 150m situated 200m off-hole at a depth below surface of less than 200m provides a suitable match between the observed and modelled data. This model incorporates a "smoke-ring" effect into the modelled response in early channels.

Both models provide suitable geological settings. The match between observed and modelled data is better for the latter of the two proposed scenarios. In addition, comparison of surface gradient array IP data show evidence of a low resistivity zone coincident with the modelled EM response off-section from MS08 and dipping east. Available evidence and the better modelled fit must be considered to support the latter of the two proposed models.

Plotting the decay with time of the model and the raw data provides a time-constant (a parameter often used to describe the quality of a conductor) in the order of 0.4-0.5 msec. This is not particularly high, however an accumulation of sulphide minerals at the Beatrice Prospect might not be expected to form a good conductor due to the lack of significant pyrite that has been associated with mineralisation intersected to date.

Recommendations have been made to log drill-holes MS7 and MS9 (being drilled at the time of writing this report) with DHEM. Results from these two holes should provide suitable evidence to either discount the anomalous response detected in MS8 or to confirm the response and better define a position to drill test the anomaly. If the anomaly is confirmed by results from MS7 and/or MS9 then it should be drilled.

2. INTRODUCTION

The Beatrice Prospect is situated within EL6/98 approximately 7 km's north of the town of Queenstown in Western Tasmania. The ground is currently being explored by Pasminco Exploration for its potential to host Rosebery style Zn-Pb-Ag-Au mineralisation within Palaeozoic volcanics and volcaniclastic sediments of the Central Mt Read Volcanics. The region also has potential for Mt Lyell style Cu-Au mineralisation.

This report presents results of a down-hole electromagnetic (DHEM) survey on diamond drill-hole MS8 conducted by Outer Rim Exploration Services for Pasminco Exploration during May 1999. The aim of the DHEM survey was to delineate anomalous conductivity response that would be directly associated with massive sulphide mineralisation, and thus provide a target for further exploratory drilling.

3. LOCAL GEOLOGY AND PREVIOUS WORK

The Beatrice Prospect comprises a prospective horizon of the Cambrian Mt Read Volcanics at the top of the Central Volcanic Complex (CVC). The CVC comprises predominantly felsic volcanics and volcaniclastics and is typically overlain by a sequence of shales, siltstones, and sandstones. It is conceptual that this contact provides a focus for mineralisation either by acting as a fluid trap and favourable geochemical position via the overlying shales, or as the sea-floor position for Koroko style VHMS mineralisation deposited during a period of quiescence. A quartz-feldspar porphyry has intruded possibly as a sill along this contact and is a prominent feature of the local geology (the Mt Sedgewick Porphyry). The Ordovician Owen Conglomerate forms topographic ridges and scree slopes that abut onto the prospective ground. Remnants of eroded Permian sediments as horizontal layered clay/silt/sand beds are also evident in the region.

The simplified local geology comprises a gently folded to steeply dipping north-south striking black shale horizon situated at the contact between overlying porphyry and underlying volcaniclastic and felsic volcanic units. Locally the black shale is intercalated with both the overlying porphyry and the underlying ashy volcanics. The black shale outcrops along a fault expressed as a present day drainage (Itac Creek) and is interpreted to dip steeply to the west and then gently fold to form an anticline in the west underlying the Mt Sedgewick Porphyry. Minor Pb-Zn mineralisation is observed in outcrop and in drill intersections within the black shale and underlying siliclastics. The two areas with potential for further mineralisation are considered to be the steeply dipping shale in the Itac Creek and the extensions of this shale (and ashes-shales-ignimbrites) that underlie the Mt Sedgewick Porphyry to the West and East of Itac Creek.

Exploration to date has focused upon the black shale units that are situated strike parallel with the Itac Creek Fault.

Previous work has been summarised by Denwer (1998) in an unpublished report for Pasminco Exploration. This work is further summarised into point form as follows:

- Stream sediment sampling and geological mapping - 1975
- Establishment of over 40 km's of gridding - 1976-present
- 38 line km's of gradient array IP surveying - 1976
- Additional soil sampling - 1977-78
- Drilling MS1, MS2, and MS3 - 1978
- EIP, DHIP, dipole-dipole, and pole-dipole IP geophysical surveys (SCINTREX) - 1978
- Drilling MS4, and MS5 - 1979
- Ground magnetics, gradient array IP, pole-dipole IP, dipole-dipole IP - 1979
- Fixed loop UTEM - 1989
- Drilling MS06 - 1996
- Drilling MS07, MS08, and MS09 - 1998-99

Drill-hole MS8 was completed at 798.7m and targeted at a geochemical anomaly on the prospective Itac Creek stratigraphy beneath the Mt Sedgewick quartz feldspar porphyry. A summary log from the drill-hole follows (taken from the Pasminco April 1999 Internal Monthly Report):

MS08 Summary Log:

From	To	
0.0	191.8	Quartz feldspar porphyry.
191.8	197.8	Volcaniclastic sandstone and shale.
197.8	292.9	Quartz feldspar porphyry.
292.9	306.2	Intercalated black shale and quartz feldspar porphyry
306.2	318.2	Black shale
318.2	344.2	Intercalated black shale and quartz feldspar porphyry (peperitic contacts)
344.2	373.7	Black shale and minor sandstone; major fault zones at 360.1-364m and 371.6-373.7m; Sphalerite-rich mineralisation in lower 2m of unit.
373.7	447.3	Quartz feldspar porphyry. Strongly Sil-Co-Chl±Kfs veined with weak sphalerite>galena minerlaisation.
447.3	583.3	Black shale and minor siltstone/sandstone. Sphalerite> galena Mineralisation from 557 - 583.3m.
583.3	651.6	Quartz feldspar porphyry
651.6	665.4	Ash volcaniclastic and minor volcaniclastic sandstone. Generally 0.5-1.0% sphalerite, but, up to 5% sphalerite in matrix of sandstone units.
665.4	696.5	Volcaniclastic sandstones (pumiceous) with trace sphalerite.
696.5	787.3	Intercalated shale and volcaniclastic ash to sandstone units. Variable Py±Sp>Gn mineralisation; narrow intervals of up to 10% Sp (in sandstone beds) but generally <0.5% Sp.
787.3	798.7	Volcaniclastic sandstone/breccia with Sil+ Kfs/hem alteration. Only trace Py+Cpy.

4. SURVEY SPECIFICATIONS

The survey was initially attempted by Pasminco Exploration staff using the Pasminco CRONE PEM system. Problems were encountered with the PEM Transmitter early in the survey and Outer Rim Exploration Services were commissioned to complete the survey using a replacement transmitter coupled to the Pasminco system.

The survey specifications are tabulated below:

Date of Survey:	May 1999
Contractor:	Outer Rim Exploration Services
Survey Type:	DHEM
System:	CRONE PEM
No. of Drillholes:	1 (MS08)
Components:	Axial (A) and cross-components (U and V)
Station Spacing:	10m (A) and 20m (U and V)
Time Base:	10 msec
Channels:	18 including the PP field
Ramp Time:	500 µsec
Synchronisation:	Cable
Transmitter Size:	600m x 400m
Current:	4.3 Amps

The method of data noise and repeatability control was as follows:

- Three readings were taken at every station and compared for repeatability. Additional readings were taken as required.

Two transmitter loop positions were utilised. For reference within the text of this report these have been labelled BEM1 (western loop) and BEM2 (eastern loop). The location of these loops is presented in Figure 1. Corner coordinates in local and AMG grid are provided on Figure 1. Down-hole survey details are provided below:

MS08 Collar East: 385110 North: 5348260 RL:955.0

Azimuth	Dip	Distance
111.0	60.0	29
112.0	60.5	71
115.0	60.5	50
116.5	60.5	150
118.0	60.8	50
118.0	60.5	50
121.0	60.3	150
120.0	60.0	107
120.0	60.0	141

Time gates utilised by the CRONE PEM system are tabulated below (msec after ramp cessation):

CHANNEL	DELAY	WIDTH
1 (PP)	-0.198	0.1
2	0.08999	0.02701
3	0.11705	0.02710

16	3.49850	0.90500
17	4.53600	1.17000
18	5.88350	1.52500

5. MODELLING PARAMETERS

Data were modelled using the FILAMENT modeling software invoked through the EMVISION EM modelling and visualisation package. The FILAMENT software is capable of inversion of results to provide minimum error between observed and modelled data, however computer inversion can have the undesirable outcome of producing non-geologically feasible results due to the non-uniqueness of solution. It is for this reason that the software was used only in the forward modeling mode for modelling MS8.

6. DISCUSSION AND RESULTS

Stacked profiles of the down-hole response are presented in Plan 1 to Plan 6. Results from each loop are discussed separately and then summarised.

BEM 1

Early-time axial data (channels 1-5) show a negative to positive cross-over down the hole. The negative peak is centred at 200m and the positive peak at 480m. The overall wavelength of this feature is in-excess of 500m and the decay is extremely rapid with time (the response has dissipated by channel 6 at 0.25 msec). Analysis of the U and V component data show a similar early-time response with U and V component data exhibiting a positive to negative cross-over down the hole. This early-time response can be explained as a current channelling effect through the thick black shale unit intersected from 447-583m. The cross-over in the V component is explained by either an oblique angle of intersection of the drill-hole with the shale or a northerly plunge. The U and A component data are easily explained with simple physics associated with the direction of current channelling (south to north).

Late-time data provide evidence of; a negative response in the A component centred at 460m; a broad positive response in the U component centred on 460m; and a positive response in the V centred on 440m. The amplitudes are very small and lie within the noise envelope (< $1nV/Am^2$) at channel 8-12. A possible explanation is a poorly coupled conductor off-section to the south of the drill-hole dipping to the east parallel to the interpreted position of the shale intersected at 447-583m and sub-parallel to the drill-hole. The response is not at all well defined and the causative body is not able to be modelled with a high degree of confidence.

BEM2

Data from the second transmitter loop do not show a corresponding early-time response to that seen with BEM1. This further confirms evidence of a current channelling source for the early-time anomaly observed with the BEM1 data (ie BEM2 is situated over the drill-hole and thus would not induce a current channelling response; if the response was inductive, then one would expect to see a response in data from BEM2).

Late-time data from BEM2 provide strong evidence for the existence of an off-hole inductive EM source. U component data from channel 7-12 (0.33-1.23msec) show a negative trough with a wavelength in-excess of 400m centred at 340m down-hole. The wavelength suggests a large causative body some distance (several hundred metres) off-hole. The polarity and location of the response suggests and inductive source rather than a current channelling source and thus provides an interesting target for further investigation. NB// Current channelling might relate only to resistivity contrasts and hence would give a response associated with moderately conductive shales in a very resistive porphyry. An inductive source suggests induced current flow in a conductor, requiring a large accumulation of conductive minerals.

Decay analysis was conducted on the data yielding a parameter known as a time-constant of 0.4-0.5 msec. The time-constant is a parameter often used to describe the quality of a conductor. The larger the time-constant the better the conductor (more conductive minerals and larger size). For reference, the time-constant of the Hellyer deposit was in the order of 2-3 msec. The fact that mineralisation intersected to date at the Beatrice Prospect is sphalerite rich (very low in conductive sulphides) can be used to make the assumption that a large accumulation of sulphides in that area would also be sphalerite rich, hence it would most likely have a poor quality EM response with a very low time-constant (if it could be seen at all, - eg Hercules).

Modelling of the EM data using the FILAMENT algorithm provides a suitable model fit between observed and modelled data with two geologically feasible solutions. These are described below:

1. A near-surface conductor striking N-S (grid) situated in the south-east corner of the BEM2 loop dipping to the west. This position is coincident with the Itac Creek Fault and the Itac Creek Shale. The inverted ring filament providing a suitable fit between modelled and observed data has a radius in-excess of 100m and dips to the west with an eastern margin defined by the Itac Creek Fault. The fact that the transmitter loop side lies directly over the position of the Itac Creek Fault and adjacent Itac Creek Shales may have had the consequence of the high amplitude energising field near the loop causing local currents to be induced in the shale/and or fault. FILAMENT modelling results from channel 12 (1.23 msec) are displayed in Figure 2. The ring filament used to describe the target has the following geometrical characteristics. The centre of this ring filament would provide the focus for any drill targeting to intersect the conductor.

East: -855E
North: 1615N
RL: 670mRL
Radius: 155m
Azimuth: 190 degrees from grid N (note on Figure 2 the azimuth is given as the dip direction ie 280 degrees).
Dip: 54 degrees to the west (note on Figure 2 the dip is given as an inclination from horizontal).

2. A source striking grid N-S situated off-section and parallel to the drill-hole MS08. An east dipping ring filament with a radius of approximately 150m situated 200m off-hole at a depth below surface of less than 200m provides a suitable match between the observed and modelled data. This model incorporates a "smoke-ring" effect into the modelled response in early channels. The "smoke-ring" is represented by the large ring filament deep below the drill-hole in Figure 3. FILAMENT modelling results from channel 8 (0.43 msec) are displayed in Figure 3. The ring filament used to describe the target has the following geometrical characteristics. The centre of this ring filament would provide the focus for any drill targeting to intersect the conductor.

East: -1100E
North: 1560N
RL: 675mRL

Radius: 155m
Azimuth: 166 degrees from grid N (note on Figure 3 the azimuth is given as the dip direction ie 76 degrees).
Dip: 36 degrees to the east (note on Figure 2 the dip is given as an inclination from horizontal).

Both models provide suitable geological settings. The match between observed and modelled data is better for the latter of the two proposed scenarios. In addition, comparison of surface gradient array IP data show evidence of a low resistivity zone coincident with the modelled EM response off-section from MS08 and dipping east. UTEM data acquired over the same position do not provide evidence for a shallow conductor. This discrepancy has not been resolved.

7. RECOMMENDATIONS

Evidence is provided for the presence of a sizeable inductive EM source situated to the south of drill-hole MS08. Drill-holes MS07 and MS09 (being drilled at the time of writing this report) should be logged with DHEM to determine whether support can be provided for the existence and modelled position of this delineated off-hole conductor. If the conductor is confirmed by results from MS07 and/or MS09 then it should be recommended to position a drill-hole to intersect the refined model position.

Data from MS08 were typically noisy (as experienced throughout much of Tasmania). The anomalous response detected from DHEM logging of MS08 was delineated largely from within the noise envelope. Future logging in the region should be conducted bearing this in mind. Practices that could facilitate better data quality are:

- Acquisition of a sample interval of 5m to allow along line spatial filtering of the EM response.
- Acquisition of 5 data samples (512 stacks) per station rather than 3.
- Application of a larger magnetic moment primary field by decreasing loop resistance with thicker transmitter loop wire.
- Application of a larger magnetic moment primary field by using a higher voltage output transmitter (240V).

1. SUMMARY

During September 1999 down-hole electromagnetic data (DHEM) using the CRONE PEM system were acquired on diamond drill-hole MS10 at the Beatrice Prospect. The Beatrice Prospect is situated in Western Tasmania within EL 6/98 approximately 7 kilometres north of the town of Queenstown. Outer-Rim Exploration Services were commissioned to complete the DHEM survey for Pasminco Exploration who are currently exploring the ground for Rosebery style Zn-Pb-Ag-Au mineralisation. Data were acquired using the CRONE DHEM time domain electromagnetic system. The survey was conducted by Outer Rim Exploration Services using the Pasminco Exploration CRONE PEM equipment with the exception of the axial probe and transmitter which were supplied by Outer Rim.

The aim of the DHEM survey was to delineate anomalous EM response that could be attributed to massive sulphide mineralisation for the purpose of defining further drill targets in the vicinity of drill-hole MS10. It is estimated that the DHEM technique would effectively explore within a 200 metre radius of the current drill-hole position. It must be considered that when reviewing this SUMMARY, and when applying the DHEM technique, that economic sulphide mineralisation may not necessarily provide a recognisable response (eg Hercules, Western Tasmania), and that some geological conditions provide anomalous EM response that is not associated with economic sulphide mineralisation (eg graphitic/pyritic black shales).

DHEM data were acquired in the time-domain using an impulse response (square-wave signal) CRONE PEM system. Data were acquired on 18 separate channels (including the "Primary Field" or PP measurement) on a 10 msec timebase. Three-component data were collected at 10 m intervals for the entire length of the 650m drill-hole. One transmitter loop was used for logging MS10. The X-Y cross-component data quite obviously show excessive noise that must be attributable to equipment fault. The data are useful, however, it is strongly recommended that the X-Y probe not be used on future surveys unless this problem can be rectified.

DHEM results from MS10 indicate the presence of an EM response centred at approximately 290 m down-hole. A sharp shoulder to this EM response at 370 m is coincident with the boundary between poorly-moderately conductive black shales and highly resistive ashy volcanics and coarser sediments. It is most likely that the response observed in MS10 is due to more conductive parts of the black shale unit. The decay rate of the response is exactly the same as the decay observed in the similar responses observed in DHEM data in near-by drill-holes MS07 and MS08. The exact location and geometry of the source of the response is not able to be adequately explained using available modelling techniques. This has been a large problem with regard to interpretation of the data. Ambiguities are thought to be due to complex geological setting and conductive host rocks. Nonetheless it is currently thought that the only responses observed at Beatrice in DHEM data to date is that of conductive host lithologies. No drill targets are clearly obvious. A Hellyer style EM response should be clearly recognisable in the Beatrice EM environment (and such a response is definitely not evident in data collected thus far) hence continued application of the technique is justified.

2. INTRODUCTION

The Beatrice Prospect is situated within EL6/98 approximately 7 km's north of the town of Queenstown in Western Tasmania. The ground is currently being explored by Pasminco Exploration for its potential to host Rosebery style Zn-Pb-Ag-Au mineralisation within Palaeozoic volcanics and volcaniclastic sediments of the Central Mt Read Volcanics. The region also has potential for Mt Lyell style Cu-Au mineralisation.

This report presents results of a down-hole electromagnetic (DHEM) survey on diamond drill-hole MS10 conducted by Outer Rim Exploration Services for Pasminco Exploration during August 1999. The aim of the DHEM survey was to delineate anomalous conductivity response that would be directly associated with massive sulphide mineralisation, and thus provide a target for further exploratory drilling. Previous DHEM logging conducted on nearby drillholes (MS07, MS08, and MS09 Dauth 1999) during 1999 indicate that the host lithologies at Beatrice do produce anomalous DHEM response. This needs to be taken into account when interpreting the data to avoid targeting of host rock EM responses.

3. LOCAL GEOLOGY AND PREVIOUS WORK

This summary of the geology and previous work is taken from the previous report on DHEM results on MS08 (Dauth 1999).

The Beatrice Prospect comprises a prospective horizon of the Cambrian Mt Read Volcanics at the top of the Central Volcanic Complex (CVC). The CVC comprises predominantly felsic volcanics and volcaniclastics and is typically overlain by a sequence of shales, siltstones, and sandstones (interpreted to be Lower Tyndall Group). It is conceptual that this contact provides a focus for mineralisation either by acting as a fluid trap and favourable geochemical position via the overlying shales, or as the sea-floor position for Koroko style VHMS mineralisation deposited during a period of quiescence. A quartz-feldspar porphyry has intruded possibly as a sill along this contact and is a prominent feature of the local geology (the Mt Sedgewick Porphyry). The Ordovician Owen Conglomerate forms topographic ridges and scree slopes that abut onto the prospective ground. Remnants of eroded Permian sediments as horizontal layered clay/silt/sand beds are also evident in the region.

The simplified local geology comprises a gently folded to steeply dipping north-south striking black shale horizon situated at the contact between overlying porphyry and underlying volcaniclastic and felsic volcanic units. Locally the black shale is intercalated with both the overlying porphyry and the underlying ashy volcanics. The black shale outcrops along a fault expressed as a present day drainage (Itac Creek) and is interpreted to dip steeply to the west and then gently fold to form an anticline in the west underlying the Mt Sedgewick Porphyry. Minor Pb-Zn mineralisation is observed in outcrop and in drill intersections within the black shale and underlying siliclastics. The two areas with potential for further mineralisation are considered to be the steeply dipping shale in the Itac Creek and the extensions of this shale (and ashes-shales-ignimbrites) that underlie the Mt Sedgewick Porphyry to the West and East of Itac Creek.

Exploration to date has focused upon the black shale units that are situated strike parallel with the Itac Creek Fault.

Previous work has been summarised by Denwer (1998) in an unpublished report for Pasminco Exploration. This work is further summarised into point form as follows:

- Stream sediment sampling and geological mapping - 1975
- Establishment of over 40 km's of gridding - 1976-present
- 38 line km's of gradient array IP surveying - 1976
- Additional soil sampling - 1977-78
- Drilling MS1, MS2, and MS3 - 1978
- EIP, DHIP, dipole-dipole, and pole-dipole IP geophysical surveys (SCINTREX) - 1978
- Drilling MS4, and MS5 - 1979
- Ground magnetics, gradient array IP, pole-dipole IP, dipole-dipole IP - 1979
- Fixed loop UTEM - 1989
- Drilling MS06 - 1996
- Drilling and DHEM logging; MS07, MS08, and MS09 - 1998-99

Drillhole MS10 was drilled to test a surface geochemical anomaly. The hole is collared at 385348mE, 5347910mN, and 739.1mRL. The hole survey details are provided in the contractor report APPENDIX I. A summary geological log follows:

0 - 21 m	Black shale
21 - 71 m	Quartz Feldspar Porphyry
71- 72 m	Itat Creek Fault
72 - 98 m	Strongly broken quartz carbonate veined black shale
98 - 263 m	Black shale (172-183 m shear/fault)
263 - 311 m	Quartz Feldspar Porphyry
311 - 350 m	Black shale
350 - 374 m	Pyrrhotitic and pyritic black shale
374 - 548 m	Ashy volcanics, minor shale, limestone, conglomerate
548 - 596 m	Black shale pyritic, interbedded with ashy volcanics
596 - 625 m	Ashy volcanic
625 - 635 m	Ashy volcanic interbedded with felsic volcanic
635 - 656.4m	Feldspar phyric volcanic

The drill-hole is interpreted to drill through the hanging wall of the easterly dipping Itat Creek Fault then into the core of a synclinal structure of folded black shale, porphyry, an ashy volcanics. The greatest potential for a large tonnage base-metal sulphide orebody is as a strataform body within the ashy volcanic interval below 374 m (ie the postulated equivalent Rosebery position). Therefore the primary target for a DHEM survey is to define anomalous response below that depth. Above 374 m experience has shown that the host lithologies (black shale and a black shale/porphyry pepperite) can produce anomalous EM response that could mask a weakly conductive mineralised system (ie galena/pyrite poor and sphalerite rich).

4. SURVEY SPECIFICATIONS

The survey conducted by Outer Rim Exploration Services using the CRONE PEM system. The Pasminco CRONE system was used for the survey with the exception of the axial probe and the transmitter which were supplied by Outer Rim Exploration Services.

The survey specifications are tabulated below:

Date of Survey:	September 1999
Contractor:	Outer Rim Exploration Services
Survey Type:	DHEM
System:	CRONE PEM
No. of Drillholes:	1 MS10
Components:	Axial (A) and cross-components (U and V)
Station Spacing:	10m (A, U, and V)
Time Base:	10 msec
Channels:	18 including the PP field
Ramp Time:	500 μsec
Synchronisation:	Cable
Transmitter Size:	600m x 400m
Current:	4.3A Amps

The method of data noise and repeatability control was as follows:

- Two readings were taken at every station and compared for repeatability. Additional readings were taken as required.

Only one transmitter loop position was utilised for MS10. For reference within the text of this report the loops has been labelled BEM2. The location of transmitter loops is presented in Figure 2. Transmitter loop corner coordinates for all loops that have been used at Beatrice in the past (local and AMG) are provided below:

Loop	Corner	Local East	Local North	AMG East	AMG North	RL
BEM1	NW	-1700	2200	385020	5348712	990
BEM1	NE	-1350	2200	385310	5348546	1045
BEM1	SE	-1100	1600	385161	5347919	820
BEM1	SW	-1650	1600	384718	5348205	870
BEM2	NW	-1350	2200	385310	5348546	1045
BEM2	NE	-950	2200	385632	5348347	910
BEM2	SE	-800	1600	385414	5347766	740
BEM2	SW	-1100	1600	385161	5347919	820
BEM3	NW	-1600	1225	385060	5347985	815
BEM3	NE	-1600	800	385410	5347770	740
BEM3	SE	-1200	1200	384830	5347650	670
BEM3	SW	-1200	850	385120	5347475	680
BEM4	NW	-1600	800	385410	5347770	740
BEM4	NE	-1600	500	385655	5347610	830
BEM4	SE	-1200	500	385470	5347300	710
BEM4	SW	-1200	850	385120	5347475	680

Time gates utilised by the CRONE PEM system are tabulated below (msec after ramp cessation):
NB. The contractor report (APPENDIX I) uses a system whereby the number 1 channel is the channel that follows the PP channel.

CHANNEL	DELAY	WIDTH
1 (PP)	-0.198	0.1
2	0.05625	0.01349
3	0.07425	0.02251
4	0.09900	0.02700
5	0.13280	0.04060
6	0.17790	0.04960
7	0.23635	0.06730
8	0.31500	0.09000
9	0.42075	0.12150
10	0.56020	0.15740
11	0.74470	0.21160
12	0.98975	0.27850
13	1.31350	0.36900
14	1.74550	0.49500
15	2.31950	0.65300
16	3.08000	0.86800
17	4.09000	1.15200
18	5.42900	1.52600

5. MODELLING PARAMETERS

Data were modelled using the FILAMENT modeling software invoked through the EMVISION EM modelling and visualisation package. The FILAMENT software is capable of inversion of results to provide minimum error between observed and modelled data, however computer inversion can have the undesirable outcome of producing non-geologically feasible results due to the non-uniqueness of solution. This is particularly the case whereby DHEM response is made complicated through superposition of response from multiple sources. It is for this reason that the software was used only in the forward modeling mode for modelling MS10.

6. DISCUSSION AND RESULTS

Stacked profiles of the down-hole response are presented in the contractors report as APPENDIX I. Results are discussed below

MS10

Axial and cross-component data show evidence for several DHEM responses.

A narrow weak in-hole response is observed at 180 m down-hole coincident with a fault/shear zone indicated in the geological log. The Itat Creek Fault does not produce an anomalous in-hole response.

A broad early-time axial component positive response migrating to late-time negative axial component is observed from 80-370 m. This is precisely coincident with the intersection of black shale in MS10. Similar responses were observed in previous DHEM logs at the Beatrice Prospect. It is most likely that response observed in MS10 is due to the host lithology (ie black shale). The response clearly has an off-hole component indicating more conductive parts of the black shale exist off-hole. Decay analysis indicates a time-constant of 0.43 msec from the axial component data. This is equivalent to the time-constants determined from responses observed in drill-holes MS07 and MS08.

U component data (referred to as X component in APPENDIX I) exhibit a broad late-time (channel 6-10) negative centred at about 400 m down-hole. The V component data (referred to as Y component in APPENI I) exhibit a broad positive to negative cross-over at late-time (channel 6-10) centred on 400 m down-hole. Modelling is unable to resolve the position of a single conductor that would conform with known geology. Use of several conductors can suitably explain the anomaly placing two ring filaments at the following locations:

FILAMENT 1.
385410 mE
5348000 mN
510 mRL
Radius = 80 m
Azimuth = 275°
Dip = 50° to the west

FILAMENT 2.
385160 mE
5348135 mN
320 mRL
Radius = 120 m
Azimuth = 90°
Dip = 75° to the east

These two positions would correlate with electromagnetically coupled limbs of the Itat Creek Black Shale on the eastern and western side of the Itat Creek Fault respectively.

Confidence on the modelling accuracy is very low. The FILAMENT 1 model has been adequately tested by MS01 which did intersect black shales (graphitic and pyritic in places) that could explain the EM anomaly. The FILAMENT 2 model is most likely the east dipping western limb of the black shale. Processing of the data with derivative techniques would in theory (in a perfect world) be able to determine whether multiple EM sources were being detected. The relatively noisy data recorded at Beatrice would not be amenable to this kind of processing.

7. RECOMMENDATIONS

- No drill targets are recommended based upon the DHEM results from MS10.
- The DHEM logging did confirm the presence of EM conductive sources which are currently thought to be formational in origin.
- The Beatrice area comprises geological units that give rise to anomalous EM response that could easily be targeted as a conductive sulphide body. Similarly it would also be possible to discount an EM response as formational when in fact the response could be due to sulphide mineralisation. Further DHEM logging at Beatrice is recommended on the basis that an orebody response could well be significantly more conductive than the observed formational responses and thus allow easy identification, however, it must be pointed out that the technique is by no means a sterilisation method since the EM response from a poorly conducting mineralised system (sphalerite rich) might be masked by the background response.
- The X-Y cross-component data were excessively noisy (in comparison to other data acquired at the Beatrice Prospect) and it is recommended that the Pasminco CRONE X-Y probe not be used until the cause of the problem is rectified.

8. KEYWORDS AND LOCALITY

Keywords

conductivity, down-hole, electromagnetics, orebody, pyrite, sphalerite, shale, sulphides

Locality

Client	:	Pasminco Exploration
Prospect	:	Beatrice.
Area	:	Rosebery, Tas.
Survey	:	Borehole PEM Survey
Survey Period	:	21st to 23rd September, 1999
Operator	:	Adrian Page.

DAILY LOG: Pasminco Exploration - September, 1999

DATE	COMMENTS	CHARGES
20-09-99	Flew from Townsville to Burnie, picked up the Pasminco vehicle and drove to Rosebery. Organised the gear and found that the probe chargers had burned out. The Axial probe was fully charged and the receiver charger was working so I survey tomorrow. I requested replacement chargers to be sent from Townsville.	
	1 Mob. day	$ 300.00
21-09-99	Had to chase up a fuel tank as the one for the gear was missing - we used a boat fuel tank successfully for this purpose. Went out to the Beatrice prospect and dummied MS-10 to EOH at 656m. We then returned to the vehicle and moved the rest of the gear up in three loads using the six wheel drive bike. Set up and surveyed the Axial component on the hole to 650m, taking 3 repeat readings per station. Returned to Rosebery at 6.30pm. Downloaded the data and processed it.	
	SURVEY PARAMETERS:	
	Loop BEM2 :600 x 400m 385310E; 5348546N: 385161E; 5347919N: 385414E; 5347766N: 385632E; 5348347N:	
	Current :4.3 Amps Time Base :10 ms Ramp Time :0.5ms Sync :Cable	
	Hole No. **:MS-10** 385347.8E; 5347910.6N: Depth :650m Channels :17 Components :Z	
	1 Survey day	$ 500.00
22-09-99	Completed the logs and expenses and reviewed the Axial data. Sent the digital data and plots to Neil Hughes, then waited for the chargers and drill to turn up.	
	1 Standby day	$ 300.00
23-9-99	Went out to the site, set up and surveyed the X-Y components, then packed up the gear, carried it back down the hill to the truck and left the site, arriving back in Rosebery at 6.00pm.

CRONE PULSE EM SYSTEM

SYSTEM DESCRIPTION

The Crone Pulse EM system is a time domain electromagnetic method (TDEM) that utilizes an alternating pulsed primary current with a controlled shut-off and measures the rate of decay of the induced secondary field across a series of time windows during the off-time. The system uses a transmit loop of any size or shape. A portable power source feeds a transmitter which provides a precise current waveform through the loop. The receiver apparatus is moved along surface lines or down boreholes.

The transmitter cycle consists of slowly increasing the current over a few milliseconds, a constant current, abrupt linear termination of the current, and finally zero current for a selected length of time in milliseconds. The EMF created by the shutting-off of the current induces eddy currents in nearby conductive material thus setting-up a secondary magnetic field. When the primary field is terminated, this magnetic field will decay with time. The amplitude of the secondary field and the decay rate are dependent on the quality and size of the conductor. The receiver, which is synchronized to the off-time of the transmitter, measures this transient magnetic field where it cuts the surface coil or borehole probe. These readings are across fixed time windows or "channels".

SYSTEM TERMINOLOGY

Ramp Time

"Ramp time" refers to the controlled shut-off of the transmitter current. Three ramp times are selectable by the operator; 0.5ms, 1.0ms, and 1.5ms. By controlling the shut-off rather than having it depend on the loop size and current ensures that the same waveform is maintained for different loops so data can be properly compared.

The 1.5ms ramp is the normally used setting for good conductors. It keeps the early channel responses on scale and decreases the chance of overload. The faster ramp times of 1.0ms and 0.5ms will enhance the early time responses. This can be useful for weak conductors when data from the higher end of the frequency spectrum is desired.

Time Base

Time base is the length of time the transmitter current is off (it includes the ramp time). This also equals the on time of the current. Eight time bases are selectable by the operator. They include the original time bases used in the analog system as well as time bases to eliminate the effects of powerline interference. The eight time bases are as follows: compatible to analog Rx: 10.89ms, 21.79ms; 60hz powerline noise reduction: 8.33ms, 16.66ms, & 33.33ms; 50hz powerline noise reduction: 10.00ms, 20.00ms, 50.00ms and 150ms.

Since readings are taken during the off cycles, the time base will have an effect on the receiver channels. Normally, a standard time base is selected for the type of system and survey being used, but this can be changed to suit a particular situation. A longer time base is preferred for conductors of greater time constants, and in surveys such as resistive soundings where more channels are desired.

Zero Time Set

The term "zero time set" or "ZTS" refers to the starting point for the receiver channel measurements. It is manually set on the receiver by the operator thus allowing adjustments for the ramp times and fine tuning for any fluctuations in the transmitter signal.

Receiver Channels

The rate of decay of the secondary field is measured across fixed time windows which occupy most of the off-time of the transmitter. These time windows are referred to as "channels". These channels are numbered in sequence with "1" being the earliest. The analog and datalogger receivers measured eight fixed channels. The digital receiver, being under software control, offers more flexibility in the channel positioning, channel width, and number of channels.

PP Channel

The PEM system monitors the primary field by taking a measurement during the current ramp and storing this information in a "PP channel". This means that data can be presented in either normalized or unnormalized formats, and additional information is available during interpretation. The PP channel data can provide useful diagnostic information and helps avoid critical errors in field polarity.

Synchronization

Since the PEM system measures the secondary field in the absence of the primary field, the receiver must be in

"sync" with the transmitter to read during the off-time. There are three synchronization methods available: cable connection, radio telemetry, and crystal clock. This flexibility enhances the operational capabilities of the system.

SURVEY METHODS

The wide frequency spectrum of data produced by a Pulse EM survey can be used to provide structural geological information as well as the direct detection of conductive or conductive associated ore deposits. The various types of survey methods, from surface and borehole, have greatly improved the chances of success in deep exploration programs. There are eight basic profiling methods as well as a resistivity sounding mode.

Moving Coil

A small, multi-turn transmitter loop (13.7m diameter) is moved for each reading while the receiver remains a fixed distance away. This method is ideal for quick reconnaissance in areas of high background conductivity.

Moving Loop

Same as Moving Coil method, but with a larger transmit loop (100 to 300 meters square). This method provides deeper penetration in areas of high background conductivity, and works best for near-vertical conductors. This method can be used in conjunction with the Moving In-loop survey for increased sensitivity to horizontal conductors.

Moving In-Loop

A transmit loop of size 100 to 300 meters square is moved for each reading while the receiver remains at the center of the loop. This method provides deep penetration in areas of very high background conductivity, and works best for near-horizontal conductors. It can be used in conjunction with the Moving Loop survey.

Large In-Loop

A very large, stationary transmit loop (800m square or more) is used, and survey lines are run inside the loop. This mode provides very deep penetration (700m or more) and couples best with shallow dip conductors (<45 deg.) under the loop.

Deepem

A large, stationary transmit loop is used, and survey lines are run outside the loop. This mode provides very deep penetration, and couples best with steeply dipping conductors (>45 deg.) outside the loop.

Borehole (Z Component only)

Isolated Borehole: A drill hole is surveyed by lowering a probe down a hole and surveying it with a number of transmit loops laid out on surface. The data from multiple loops gives directional information on the conductors.

Multiple Boreholes: One large transmit loop is used to survey a number of closely spaced holes. The change in anomaly from hole to hole provides directional information.

These methods have detected conductors to depths of 2500m from surface and up to 200m from the hole.

3-D Borehole

Drill holes are surveyed with both the Z and the XY borehole probes. The X and Y components provide accurate direction information using just one transmit loop.

Since the probe rotates as it moves down the hole a correction is required for the X-Y data. This is accomplished in one of two ways. The standard approach is to use the measurement of the primary field from the "PP" channel, apply a "cleaning" algorithm to remove most of the secondary field contamination, and compare this to theoretical values. The amount of probe rotation is then calculated, and the correction can be made. The second method involves the use of an optional orientation device for the X-Y probe which is produced in cooperation with IFG Corp. This attachment uses dipmeters to calculate the probe rotation.

Underground Borehole

Underground drill holes can be surveyed in any of the above mentioned borehole methods with one or more transmit loops on the surface. Near-horizontal holes can be surveyed using a push-rod system.

Resistivity Soundings

By reading a large number of channels in the centre of a transmit loop it is possible to preform a decay curve analysis giving a best-fit layer earth model using programs such as ARRTI or TEMIX.

EQUIPMENT

Transmit Loops

The PEM system can operate with practically any size of transmit loop, from a multi-turn circular loop 13.7m in diameter, to a 1 or 2 turn loop of any shape up to 1 or 2 kilometers square using standard insulated copper wire of 10 or 12 gauge. The multi-turn loop is made in two sections with screw connectors. The 10 or 12 gauge loop wire comes on spools in either 300m or 400m lengths.

Power Supply

The PEM system normally operates with an input voltage from 24v to 120v. The maximum current is 20 amps in a single loop but the effective current can be increased by doubling the loop wire in series. For low power surveys a 20amp/hr 24v battery can be used. The power supply requires a motor generator and a voltage regulator to control and filter the input voltage to the transmitter.

Specifications: PEM Motor Generator

- 4.5 hp Wisconsin, (2 kw)
- belt drive to D.C. alternator
- cable output to regulator
- maximum output: 120v, 20amp (2 kw);
- fuse type overload protection
- steel frame
- external gas tank
- unit weight: 33kg (2 kw); 52kg (4 kw)

Specifications: PEM Variable Voltage Regulator

- selectable voltage between 24v and 120v or 48v and 240v
- 20amp maximum current
- fuse and internal circuit breaker protection

Transmitter

The transmitter controls the bi-polar on-off waveform and linear current shut-off ramp. The latest 2000w PEM Transmitter has the following specifications:

Specifications: PEM Transmitter

- time bases: 10.89ms, 21.79ms, 8.88ms, 16.66ms, 33.33ms, 10ms, 20ms, 50ms 150ms.
- ramp times: 0.5ms, 1.0ms, 1.5ms
- operating voltage: 24v to 120v (2 kw); 48v to 240v (4 kw)
- output current: 5amp to 20amp
- monitors for input voltage, output current, shut-off ramp, tx loop continuity, instrument temperature, and overload output current
- automatic shut-off for open loop, high instrument temperature, and overload
- fuse and circuit breaker overload protection
- three sync modes: 1) built-in radio and antenna
  2) cable sync output for direct wire link to receiver or remote radio
  3) connectors for the crystal clock

Receiver

The receivers measure the rate of decay of the secondary field across several time channels. Three types of receivers are available with the PEM system: Analog Rx, Datalogger Rx, and Digital Rx. The Analog Rx and Datalogger Rx read eight fixed time channels while the Digital Rx, under software control, offers a variety of channel configurations. The Digital Rx has been used in the field for contract surveys since 1987.

Specifications: Digital PEM Receiver

- operating temperature -40°C to 50°C
- unit weight 15kg; shipping weight 25.5kg

Hardware:

- 24v rechargeable gel cell battery supply
- two CMOS microprocessors (NSC800)
- alphanumeric keyboard

- 2 x 16 character cold weather display
- 16 x 40 character (256 x 128 pixels graphic) display
- 64k byte solid state memory storage
- cable, radio or crystal clock synchronization
- RS-232 serial I/O

Sampling process features:
- 16 bit A/D conversion
- digital recording of data in nano-tesla/sec
- rejection of atmospheric noise samples based on digital threshold detection
- automatic gain control to optimize receiver signal to noise ratio

Menu driven operating software system offering the following functions:
- controls channel positions, channel widths, and number of channels using a basic slice of 4.5µsec
- time bases: 10.89ms, 21.79ms, 8.88ms, 16.66ms, 33.33ms, 10ms, 20ms, 50ms and 150ms
- ramp time selectable in 4.5µsec steps
- sample stacking from 512 to 65536
- scrolling routines for viewing data
- graphic display of decay curve and profile with various plotting options
- routines for memory management
- control of data transmission
- provides information on instrument and operating status

Sync Equipment

There are three modes of synchronization available; radio, cable, and crystal clock. The radio sync signal can be transmitted through a booster antenna from either the PEM Transmitter internal radio or through a Remote Radio.

Specifications: Sync Cable
- 2 conductor, 24awg, teflon coated
- approx. 900m per aluminum spool with connectors

Specifications: Remote Radio
- operating frequency 27.12mhz
- 12v rechargeable gel cell battery supply
- fuse protection
- sync wire link to transmitter
- coaxial link to booster antenna

Specifications: Booster Antenna
- 8m, 4 section aluminum mast
- guide rope support
- ¼ wave CB fiberglass antenna
- range up to 2km
- coaxial connection to transmitter or remote radio

Specification: Crystal Clocks
- heat stabilized crystals
- 24v rechargeable gel cell battery supply
- rx unit can be separate or housed in the receiver
- outlet for external supplementary battery supply

Surface PEM Receive Coil

The Surface PEM Receive Coil picks up the EM field to be measured by the receiver. The coil is mounted on a tripod that can be positioned to take readings of any component of the field.

Specifications: Surface PEM Receive Coil
- ferrite core antenna
- built-in preamplifier
- VLF filter
- 10khz bandwidth
- 23:1 amplifier gain
- two 9v transistor battery supply
- tripod adjustable to all planes

Borehole PEM Z Component Probe

The Z component probe measures the axial component of the EM field. The Z component data is not affected

by probe rotation so no correction are required.

645536

Specifications: Borehole PEM Z Component Probe

- ferrite core
- built-in preamplifier
- dimensions: length - 1.6m; dia - 3.02cm (3.15cm for high pressure tested probes)
- internal rechargeable ni-cad battery supply
- replaceable heat shrink tubing for abrasion protection
- pressure tested for depths 2800m

Borehole PEM XY Component Probe

The XY probe measures two orthogonal components of the EM field perpendicular to the axis of the hole. Correction for probe rotation can be achieved by two methods. The standard approach is to use the measurement of the primary field from the "PP" channel, apply a "cleaning" algorithm to remove most of the secondary field contamination, and compare this to theoretical values. The amount of probe rotation is then calculated, and the correction can be made. The second method involves the use of an optional orientation device for the X-Y probe that uses dipmeters to calculate the probe rotation.

Specifications: Borehole PEM XY Component Probe

- ferrite core
- built-in preamplifier
- dimensions: length - 2.01m; dia - 3.02cm
- internal rechargeable ni-cad battery supply
- selection of X or Y coils by means of a swich box on surface or automatic switching with Digital receiver
- replaceable heat shrink tubing for abrasion protection
- pressure tested for depths to 2800m

Orientation Device

The orientation device is an optional attachment for the XY probe which measures the rotation of the probe using two dipmeters.

Specifications: Orientation Device

- 2 axis tilt sensors
- sensitivity +/- 0.1 deg.
- operating range -89.5 to -10 deg.
- dimensions: length - 0.94m; dia - 28.5cm

Borehole Equipment

To lower the probe down a drill hole requires a cable and spool, winch assembly frame and cable counter. Borehole surveys also require equipment to "dummy probe" the hole before doing the survey.

Specifications: Borehole Cable

- two conductor shielded cable
- kevlar strengthened
- currently 1500m but will shortly have cabability of surveying to depths of 3000m.

Specifications: Slip Ring

- attaches to side of borehole cable spool providing a connection to the receiver while allowing the spool to turn.
- VLF filter
- pure silver contacts

Specifications: Borehole Counter

- attaches to the drill hole casing
- calibrated in meters

Specifications: Dummy Probe and Cable

- solid steel or steel pipe
- same dimensions as borehole probe
- shear pin connection to dummy cable

331908	42	1795	174000	9530	33	18200	13.1	4.6	40000	Dump sample from Lk. Dora mine; Field sample no.10; possibly tr Gn in sample
331909	45	838	106000	115	35	25500	7.1	4.0	23500	Dump sample; Field sample no.10
331910	40	1815	56000	2080	35	574	3.6	4.9	1045	o/c;Field sample no.12
331911	21	269	68500	3290	-10	656	3.3	6.4	1080	Dump sample from small pit, Field sample no.13
331912	28	37	77000	6030	13	165	3.5	3.6	616	Dump sample from small pit, Field sample no.14
331913	7	79	59500	19	-10	205	3.1	5.3	295	o/c;Field sample no.15
331914	28	15	172000	8420	-10	211	2.8	3.4	679	o/c from a small pit; Field sample no.16
331915	42	36	113000	5390	24	84	3.5	3.4	382	Field sample no.17(i) from location 120
331916	33	1795	118000	5310	-10	121	2.0	2.9	871	Field sample no.17(ii) from location 141.
331917	47	1315	86000	3310	-10	36	1.8	2.4	346	Field sample no.18 from location 142
331918	8	103	27000	1660	-10	2600	2.8	2.9	643	Field sample no.20 from location 220, Dump sample.
331919	7	195	24500	2060	-10	8950	2.1	2.7	403	Field sample no.21 from location 220. Dump sample.
331920	8	411	22500	645	-10	10700	2.8	2.8	1665	Field sample no.22, location 220. Dump sample.
331921	20	93	70000	6640	40	4090	6.2	4.2	9250	Field sample no.23, location 46. Dump sample.
331922	12	13800	72500	3670	22	64	4.5	3.2	226	Field sample no.25. Dump sample from adit below location 1
331923	9	453	41000	1390	-10	366	3.6	4.3	338	Field sample no.26, from location 225, dump sample from northern pit.
331924	41	705	211000	3920	10	1490	4.9	12.3	1810	Field sample no.29, from location 235-wallrock to mag. veins(sample 331925)
331925	43	357	398000	3970	-10	3190	4.7	44.8	4150	Field sample no.29, from location 235-mag. veined material
331926	15	331	596000	1790	-10	416	3.7	36.8	620	Field sample no.31 from location 237, magnetite veined-chl alt. volc.
331927	82	1495	106000	665	-10	13000	15.4	10.9	12300	Field sample no.32from location 241, sample of sulphide-rich zone from dump.
331928	87	2980	203000	2110	-10	3730	10.2	7.3	12100	Field sample no.32 from location 241. Dump sample of min. + host rock
331929	40	3210	237000	41	12	1345	3.4	13.5	3050	Field sample no. 33 from location 242. magnetite veined material from dump
331930	41	3580	225000	5090	15	880	3.2	15.3	1505	Field sample no.33 from location 242. Most rock to mag veined zone. Dump sample.
331931	22500	38500	183000	170	105	4580	44.8	15.7	993	Field sample no.34 from location 258, dump sample of high-grade mineralisation

SampleID	Co	Cu	Fe	Mn	Ni	Pb	Sb	Sn	Zn	Comments
331932	318	948	159000	4630	-10	1370	10.1	8.0	2070	Field sample no.35 from location 258, host rock to sample 331931
331933	885	1890	79500	215	-10	431	30.3	9.3	110	Field sample no.37 from location 264, pyritic zone in Q-eye volc.
331934	80	290	92000	1120	-10	244	27.6	6.8	357	Field sample no.38, location 264, host to min of sample 331933
331935	95	1730	198000	2570	-10	1305	7.1	19.8	501	sample
331936	52	432	179000	4550	-10	2480	5.4	11.2	220	Field sample no.40, location 273, dump sample
331937	21	973	104000	32	-10	878	3.8	13.4	1595	Field sample no.41 from location 273, host to sample 331935, 331936, dump sample.
331938	47	32500	235000	2630	36	8500	5.1	6.3	17400	Field sample no.43 from location 274, dump sample of mineralisation
331939	146	4920	188000	5550	-10	4890	4.9	11.2	9330	Feild sample no.45, location 277
331940	238	2560	247000	1850	-10	9510	6.5	9.5	2330	Field sample no.45 from location 277, dump sample of min.
331941	320	5430	131000	1250	-10	21000	15.8	8.1	96500	Field sample no.45 from location 277, dump sample of min.
331942	39	1525	83500	3360	25	2620	6.0	5.1	2910	Field sample no.kd8
331960	61	195	85500	23	-10	581	4.6	3.3	1880	location 302, chlorite altered volcanic with py veins + diseminations, dump sample
331961	54	500	84000	2590	-10	842	2.2	2.1	2670	location 302; dump sample; chlorite alt volc with 3% dissem + vein pyrite
331962	33	745	91000	3590	-10	725	2.7	4.2	4400	location 312, chlorite alt. q-phyric volcanic with 0.5% disseminated pyrite, host to 311961
331963	12	141	59500	3580	-10	2890	2.6	2.7	262	pyrite
331964	99	3920	140000	108	57	3140	3.5	10.1	5350	location 308, from trench, strong chlorite altered volcaniclastic with 3% Py + cpy veins
331965	24	41	55500	2620	-10	92	0.9	4.3	383	disseminated pyrite
331966	33	1620	144000	2840	-10	277	3.7	4.8	709	pyrite, host to 967 & 968
331967	229	150	104000	1040	-10	119	11.6	7.2	294	location 330, trench sample, strongly chlorite altered q-phyric volcanic with 5% vein pyrite
331968	323	258	100000	385	-10	478	11.9	5.1	126	location 330; trench sample; altered volcanic with 10% pyrite veins
331969	111	34	48500	2	-10	328	11.4	6.9	70	location 330, trench sample, oxidised silica-sericite-pyrite rock
331970	148	293	186000	1210	-10	143	16.9	1.3	341	location 330, py (10%) veined chlorite alt. volc
331971	19	35	34000	1590	-10	90	1.9	2.5	140	field sample kd6, weak chlorite-silica altered q-phyric volc with 0.5% dissem. pyrite
