1 Introduction

1.1 Summary and Scope

The Main, No.2 and Reward tin-tungsten-magnetite deposits are part of an extensive system of greisenised skarns hosted by Neoproterozoic carbonates adjacent to the Devonian Meredith Granite in the Mt Lindsay – Stanley River area of western Tasmania, Australia. This report documents the estimation of tin (Sn), tungsten trioxide (WO_3), Mass Recovery of magnetic iron minerals (MR) and copper (Cu) for the Main , No.2 and Reward deposits based on exploration and drilling data to August 2012. The estimated Sn, WO_3, and MR resources at Sn Equivalent (SnEQ) cut-offs of 0.20 %, 0.35 % and 0.45% are summarised in Table 1. SnEQ represents the combined values of co-products Sn, WO_3 and MR normalised to the value of Sn, and was calculated as follows:

- Main and No.2 deposits SnEQ % = Sn % + (WO_3 % x 1.90459) + (MR % of magnetic Fe x 0.006510) + (Cu % x 0.28019);
- Reward deposit SnEQ % = Sn% + (WO3% x 1.65217) + (Cu% x 0.34783).

The Sn equivalent formulae uses a tin metal price of US$23,000/t, an APT (Ammonium Para Tungstate) price of US$380/mtu (1mtu =10kgs of WO_3), a magnetite concentrate price of US$110/t and a copper metal price of US$8,000/t.

Table 1: Sn, WO_3, and MR resources by SnEQ cut-offs 0.20 %, 0.35 % and 0.45 %. Reported to two significant figures.

Lower Cut-off SnEQ	Rescat	Tonnes	SnEQ %	Sn %	WO3 %	MR %	Cu ppm	Contained Sn metal (tonnes)	Contained Sn+WO_3 metal (tonnes)

A summary of the resource estimation parameters is as follows:

- For the Main and No.2 Skarns, the classification of the Resources has been based on the variography run during the Ordinary Kriging estimation process for tungsten. Measured Resources are for continuous areas where the majority of blocks are estimated within the range of the variograms, and which coincide with high levels of data quality, quantity and confidence in the geological interpretation. Indicated Resources are for continuous areas where the majority of blocks are estimated within twice the range of the variograms, and which coincide with an appropriate level of data quality, quantity and confidence in the geological interpretation. All areas outside of the Measured and Indicated Resources have been classified as Inferred.

- For the Reward Skarn, the classification of the Resources has been based on the estimation run during the Inverse Distance Weighed estimation process. Indicated Resources are for continuous areas where the majority of blocks are estimated within the range of the minimum drill hole spacing and which coincide with higher levels of data quality, quantity and confidence in the geological interpretation. All areas outside of the Indicated Resources have been classified as Inferred.
- The Resources are reported above the 0.20% and 0.45%Sn equivalent grade cut-off with no top cut applied for the Reward Skarn, whereas for Main and No.2 Skarns a top cut of 10% was applied to the tin grades and a top cut of 4% was applied to the tungsten grades.
- The reported grades and tonnages are rounded to two significant figures in accordance with recommendations of the JORC code.
- This Resource estimation covers approximately 1,300 m strike extent of the Main Skarn, 1,600 m strike extent of the No. 2 Skarn and 600 m strike extent of the Reward Skarn. The Main and No.2 Skarns are near vertical tabular bodies with local off-sets by late-stage faulting, whereas the Reward Skarn varies from being near vertical tabular bodies to shallow dipping and curved lenses.
- Some 376 diamond core drill holes for a total of 71,358 m were used to define the mineralised zones for this resource estimate, including 49 holes for 11,787m drilled by previous explorers. Of this drilling some 122 holes for 25,582 m pierced the Main Skarn , 134 holes for 27,650 m pierced the No.2 Skarn (note that six holes pierced both skarns) and 20 holes for 2,953 m pierced the Reward Skarn. Of the total 273 drill holes used for the current Resource estimation some 21 holes for 4,761 m core of mainly BQ size (36.5mm diameter) were drilled by the previous owners Aberfoyle Tin Development Partnership and Renison Limited; the other 250 drill holes for 49,767 m were drilled by Venture Minerals Limited with most of the core used in the resource estimate being HQ size (63.5mm diameter, 51% of samples) and NQ size (47.6mm diameter, 40% of samples). The rest of samples were taken from BQ size core (36.5mm diameter, 7% of samples), PQ size core (85mm diameter, 1% of samples) and less than 1% combined of samples taken from other drill methods (AX size core, percussion drilling and adit channel sampling).
- Petrography indicates the widespread occurrence of cassiterite (the saleable oxide of tin) in the three skarns. Logging with an ultraviolet lamp and petrography indicates the main tungsten mineral is scheelite.
- Pilot scale metallurgical testwork has been completed for tin, tungsten and magnetite on the Main and No.2 Skarns with results indicating that economic extraction is highly likely. The results of this testwork are stated in the ASX announcement of August 31 2012. Similarly pilot scale metallurgical testwork was completed for copper on the Main and No.2 Skarns resulting in an average recovery of 58%. Initial metallurgical testwork has been completed for tin extraction from the Reward Skarn with similar results to that achieved for the Main and No.2 Skarns.
- Drill hole density in the Main Skarn ranges from approximately 25m by 10m to a maximum of c. 120m, and the No.2 Skarn from approximately 20m by 10m to a maximum of c. 120m. Overall drill hole spacing for both skarns is very approximately 40m by 25m.The drill hole density in the Reward Skarn ranges from approximately 25m by 10m to a maximum of c. 100m.
- Some of the previous owners' drill core from both the Main Skarn and No.2 Skarn is still available and where possible re-sampled in 6 feet or 2m intervals as appropriate by Venture Minerals Limited and assayed for a broader suite of elements including tin, tungsten and iron. The remaining

core was ¼ core sampled with core saw, or in cases where only quarter core was available the entire remaining core was sampled.

- The Venture Minerals Limited drill core (NQ and HQ) was sampled by core saw in a continuous and volumetrically consistent basis in 2m intervals across the mineralised skarns.
- Documentation on the analytical techniques used by the previous owners was unavailable. Original assays from 18 of the previous owners' holes were used in the resource estimate (c.4% of total assays). The Venture Minerals Limited drill core samples were submitted to ALS Chemex (quality system complies with international standards ISO 9001:2000 and ISO 17025:2005) and SGS Renison for crushing, pulverising and assaying. All of Venture Minerals Limited's assays used for the resource estimation were done by XRF.
- There was no QC information available on the assays from the previous owners' drilling. Venture Minerals Limited's QAQC samples included standards and field duplicates which were submitted with each drill hole. The QC data is considered adequate for the current resource estimate.
- All diamond drill core was geologically logged. When the drill core was orientated then it was also structurally logged.
- The densities used in the resource estimation were based on 7,319 specific gravity measurements made on the diamond core at one meter intervals within the mineralised zones. Weathered materials which account for only c. 2% of the Sn equivalent resource estimate were assigned to a separate domain with an average density 1.7 in the Main and No.2 Skarns. Fresh rock density for the Main and No.2 Skarns was interpolated to the block model using the same technique as for grade estimation. The mean density for the Main Skarn was 3.39 t/m3, whilst for the No. 2 Skarn it was 3.58 t/m3. Densities for the Reward Skarn were interpolated to the block model using the same technique as the grade estimation. Average density was 2.21 t/m3 for the Reward Skarn.
- Drill hole collar positions for the previous owners' drilling were transformed to the MGA grid after several of the holes were relocated and surveyed. Of Venture Minerals Limited's 327 drill hole collars some 367 (93%) were surveyed in the MGA Zone 55 GDA94 grid and datum by licensed surveyors using a combination of differential GPS and total station survey systems and the remaining 26 collars (7%) were surveyed using handheld GPS.
- Some 57% of the previous owners drill holes were surveyed with a down hole camera, for which all plunge measurements and some azimuth measurements were accepted. All of Venture Minerals Limited's drill holes were surveyed with conventional magnetic instruments and, as for previous explorer data, all plunge and only consistent azimuth data were accepted. Some 2% of Venture Minerals Limited's drill holes were also surveyed by north-seeking gyroinclinometer tool by independent contractor Northern Exploration Pty Ltd, and some 63% of Venture's drill holes were surveyed with a Deviflex tool by Venture personnel using tools hired from DH Surveys Pty Ltd with another 3% receiving collar orientations only.
- The tin, tungsten and magnetite mineralisation in the Main and No.2 Skarns is not completely coincident; consequently a different set of wireframes was created for each commodity from geological cross section interpretation for this resource estimate. Four discrete wireframes were created for the magnetite and tin resources in the Main and No. 2 Skarns, three for the tungsten resource. The wireframes were then divided into geometrical subdomains, resulting in a total of 16 domains (6 for tin, 5 each for tungsten and magnetite). The wireframes were filled with blocks of 10m x 5m x 2.5m xyz dimension with 2.5x2.5x1.25m sub-blocking. The tin, tungsten trioxide, and iron grades were then interpolated to the blocks using Ordinary Kriging for each commodity separately, with an initial search ellipse of 69x53x6m for magnetite, 68x70x8m for tin and

73x40x8m for tungsten, oriented parallel to the strike and dip of the mineralised skarn and as indicated by the variography, followed by progressively more relaxed searches until all blocks were assigned a tin, tungsten trioxide, and iron grade. Four sectors were used for each search ellipse with a maximum of 10 points per sector, and a minimum of 4 points for the first search followed by more relaxed search criteria down to a minimum of 2 points for subsequent searches. The three separate block models were then combined into one model and the copper grades estimated into the new model with the Inverse Distance Squared method with an initial search ellipse of 50x25x8m oriented parallel to the strike and dip of the mineralised skarn.

- For the Reward Skarn four separate wireframes were created from geological cross section interpretation. The wireframes were filled with blocks of 10m x 5m x 2.5m xyz dimensions with 2.5x2.5x1.25m sub-blocking. The tin, tungsten and copper grades were estimated to the blocks using the Inverse Distance Squared method with an initial search ellipse of 25x25x5m oriented parallel to the strike and dip of the mineralised skarn. Four sectors were used for each search ellipse with a maximum of 6 points per sector, and a minimum of 3 points for the first search followed by 2 points for subsequent searches.
- The weight (or mass) recovery ("MR") of the iron in the Main and No.2 Skarns was determined by Davis Tube Recovery tests ("DTR") for 90% of the composited assay intervals used for the estimation. MR for the remaining assay intervals was calculated by regression of the magnetic susceptibility (7% of assay composites). It was not possible to regress MR data for approx. 3% of the assay composite intervals (historic drill holes without Fe grade or magnetic susceptibility data). MR was interpolated to the block model using the same technique as for grade estimation.

The current resource estimation indicates the presence of significant Sn, WO_3, magnetite and Cu resources within the Main, No.2 and Reward greisenised skarns in the Mt Lindsay – Stanley River area, and is intended to provide the basis for a Bankable Feasibility Study of project economics. Bench and pilot-scale investigations into the extractability of the various metals indicate that magnetite, cassiterite, scheelite and chalcopyrite can all be recovered in significant quantities. Potential for tin, tungsten and magnetite resource growth is recognised along strike of the Main, No.2 and Reward skarns, also within the adjacent Livingstone South, No.1, Waterhouse, Eastern, Reward South, Big Wilson and Merton deposits and prospects.

The information in this report from data collection to interpretation wireframes and geostatistical modelling is based on information compiled by Venture employees under the supervision of Mr Andrew Radonjic. Mr Radonjic is a full time employee of Venture Minerals and has sufficient experience to the style of mineralisation and type of deposit to qualify as competent person defined by the 2004 Edition of the "Australian Code for Reporting of Mineral Resources and Ore Reserves". Mr Radonjic consents to the inclusion in this report of the matters based on information in the form and context in which it appears.

1.2 Project Location and Access

The Mt Lindsay Tin-Tungsten-Magnetite Project is located in western Tasmania approximately 32 km by road from the nearest town Tullah (Figure 1), and is entirely included within Mining Lease 3M/2011 and Exploration Licence 21/2005 held 100% by Venture. Access to the project area is via the sealed (bitumen) Pieman Road which branches off the Murchison Highway 4 km north of Tullah, then approximately 1 to 3 km of 4WD vehicle track to the Resource sites. The Resources are within c. 3 km from Hydro Tasmania transmission lines (adjacent to the Pieman Road) and 21 km from the Bastyan hydroelectric powerhouse and Emu Bay Railway which connects with the port of Burnie approx. 95 km to the north.

Western Tasmania has over 100 years of mining history, and the most significant active or recently active mines in the region include Savage River (magnetite), Renison Bell (tin), Mount Bischoff (tin), Cleveland (tin and copper), King Island (tungsten), Rosebery (lead, zinc, silver and gold), Hellyer (lead, zinc, silver and gold), and Mt Lyell (copper). Mt Lindsay is 26 km in a direct line SSE of the Savage River magnetite mine and 14 km to the NNW of the Renison Bell tin mine.

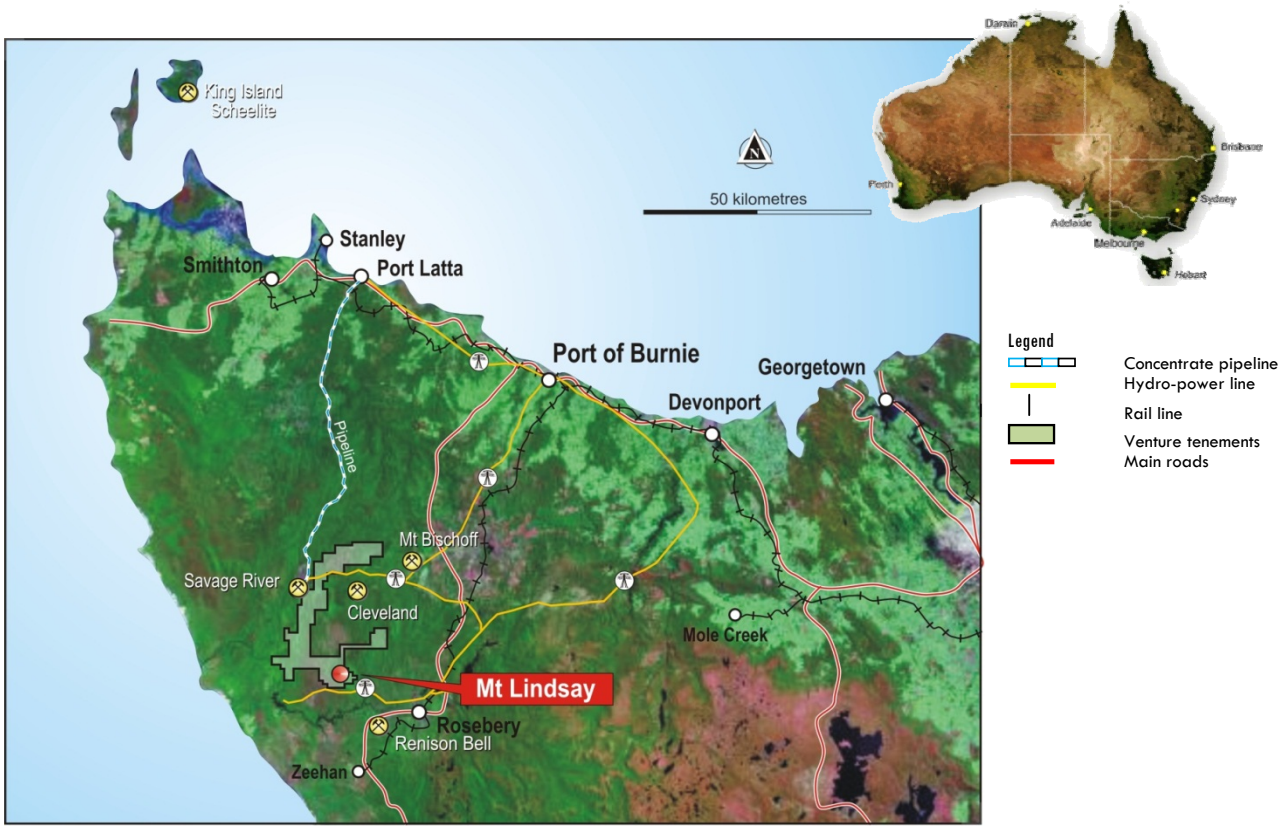

Figure 1: Mt Lindsay Project Location Plan

1.3 Exploration and Mining History

Alluvial tin was discovered in the nearby Stanley River area sometime around 1893 and subsequently developed into the Stanley River Tin Fields. Cassiterite-bearing gossans were subsequently discovered at Stanley Reward and the adjacent Mt Lindsay in the early 1900s with minor small-scale open-cut and underground tin mining occurring to about 1932. Shafts at the Stanley Reward gossan reputedly reached 150 ft, and shafts and adits into the main tin-bearing magnetite-sulfide body, now called the Main Skarn, at

Mt Lindsay reached about 30-40 m beneath surface over approx 1.1 km strike extent. Production records are incomplete, but included at least 59.8 tons of lode tin from Mt Lindsay, and at least 79.6 tons of alluvial tin.

Descriptions of mining activities and the deposit indicate the mineralisation at Mt Lindsay was mostly of the bedding-parallel sulphide and magnetite replacement type after shale, tuff and carbonate with some high-grade cassiterite veins. The stratigraphy-parallel sulphide and magnetite replacement mineralisation was evidently generally of low tin grade and most of the tin production came from the high-grade cassiterite-rich veins. The Mt Lindsay Mining Company NL recorded small amounts of ore grading up to 25 % Sn, and sampling of the abandoned workings in the 1950s (Pearson, 1952) returned up to 3 feet at 27.6 % Sn. Mining activities at Mt Lindsay had largely ceased by 1923 by which stage the oxide ore had been worked over a zone 600 m long and averaging 30 m thick. Periodic tributing of the oxide ore continued until 1932. A potentially large body of lower grade replacement tin ore remained in which the mineral assemblage was noted to comprise mainly magnetite and pyrrhotite with a wide range of silicates and variable amounts of cassiterite, pyrite, chalcopyrite, arsenopyrite and scheelite.

In his bulletin on the Stanley River Tin Field of 1914 government geologist L. L. Waterhouse noted the occurrence of iron ores of possible economic value, describing a magnetite and hematite body approximately 40 m across protruding through the alluvial flats beneath Mt Livingstone (the Livingstone Creek gossan). At that time two adits had been driven into the Livingstone Creek gossan in search of tin. Waterhouse (1914) also described c. 10-20 m thickness of cassiterite-bearing banded magnetite mineralisation within the hangingwall (southern) side of the Mt Lindsay tin lode (the Main Skarn), and a parallel zone of magnetite c. 200 m north of the Main Skarn which is now called the No.2 Skarn. While potentially significant hematite and magnetite mineralisation was recognised approximately 100 years ago, tin remained the focus for subsequent mineral exploration.

Aberfoyle Tin Development Partnership (“Aberfoyle”) took up the Mt Lindsay – Stanley River area in 1962 and over the following eight years conducted geological mapping, geophysical surveying, soil sampling, trenching and channel sampling, and 30 diamond core drill holes for 2,936 m focussing on the old Mt Lindsay mine (the Main Tin Zone or Main Zone) but also including seven drill holes on three traverses targeting the No.2 Skarn. Approximately 600 m of strike of the Main Skarn was covered by mainly single hole traverses approximately 40 m apart to a maximum vertical depth of 185 m beneath surface and mostly less than 70 m depth. Some of the better drill intercepts from the Main Skarn included 15 m at 0.77 % Sn in ML1 and 14.1 m at 1.75 % Sn in ML3. Magnetite zones were logged agreeing with descriptions by Waterhouse (1914) of the mineralisation exposed at surface, but the core was not assayed for iron or tungsten. The drill holes into the No.2 Skarn encountered low grade tin mineralisation (e.g. 12.8 m at 0.2 % Sn in hole ML2/1) and while they were not assayed for iron the drill logs again indicate the presence of massive and banded magnetite mineralisation. Several magnetic anomalies were identified parallel to the Main and No.2 skarns but remained largely untested when Aberfoyle joint ventured the project to Renison Limited (“Renison”) in 1972. The Stanley Reward and Livingstone Creek areas were surveyed with magnetometer, mapped and sampled, but the identified gossans and magnetic anomalies were not drill tested and Aberfoyle released the area before the joint venture with Renison.

Renison drilled a further 30 diamond core holes for 10,753 m at Mt Lindsay, mainly into the Main, No.1 and No.2 skarns, extending considerably the identified tin mineralisation. The drilling confirmed the presence of multiple zoned skarns prospective for tin, tungsten, copper and, although Renison were not commercially interested in it, magnetite. Renison assayed for a broader suite of elements than Aberfoyle, including W, Cu, Fe, Pb and Zn in addition to Sn. The best intercept achieved by Renison was 23 m at 30 % Fe (mainly as magnetite), 0.83% Sn and 0.04% WO_3 in ML38 from the No.2 Skarn. Metallurgical testwork and petrography on the core from ML38 indicated an abundance of cassiterite which would be amenable to normal extractive processes for tin. Renison abandoned the project in the mid 1980s after collapse of the tin price and there were no further drilling activities at Mt Lindsay until Venture Minerals Ltd ("Venture") took up the project.

The Stanley River area c. 2-4 km west of Mt Lindsay was subject to an extensive exploration programme over the 1973-1986 period by Pacminex Pty Ltd (subsidiary of CSR Ltd) and Union Corporation Pty Ltd which became Gencor (Australia) Pty Ltd. This series of companies is here collectively referred to as CSR. Exploration activities included geological mapping, ground magnetic traverses, induced polarisation surveying, a trial gravity traverse, airborne EM surveying, stream sediment, soil, auger and rock chip sampling, and 19 diamond core drill holes for 3459 m. The work indicated the presence of at least 3 km strike extent of magnetic stanniferous "Renison marker sequence" striking northwest from Stanley River along Livingstone Creek beneath a partial cover of alluvial gravels up to 10 m thick. Stanniferous gossans up to 280 m long by 40 m wide were mapped at Livingstone Creek and Stanley Reward, and were interpreted to be the surface expression of pyrrhotite-magnetite skarns replacing dolomite and shale horizons within the "Renison marker sequence". Rock chip samples from the gossans returned up to 2.37 % Sn, trench samples up to 11 m at 1.13 % Sn, and diamond drill holes LCD2 returned 10 m at 0.4 % Sn and GSR10 41 m at 0.4 % Sn along with anomalous Cu and W.

2 Geology and Mineralisation Controls

2.1 Geological Setting

The Mt Lindsay – Stanley River magnetite-tin-tungsten deposits are hosted by the Neoproterozoic Success Creek Group and Crimson Creek Formation within the southern contact metamorphic aureole of the Meredith Granite (Figure 2). The Meredith Granite is part of a suite of Devonian granites which is very important to tin-tungsten mineralisation in Tasmania, and deposits associated with this suite include the world class Renison Bell tin mine (26 Mt at 1.46 % Sn), Mount Bischoff (10.54 Mt at 1.1 % Sn), Cleveland (12.4 Mt at 0.62 % Sn, 0.25 % Cu) and King Island (17 Mt at 0.85 % $W0_3$). Cleveland and Renison Bell are the closest mined tin deposits to Mt Lindsay. Cleveland is located approx. 25 km to the north of Mt Lindsay and is hosted by a correlate of the Crimson Creek Formation, while Rension Bell situated c. 14 km to the southeast of Mt Lindsay is hosted by the uppermost Success Creek Group and basal Crimson Creek Formation.

The western part of the Mt Lindsay magnetite-tin-tungsten project includes the Success Creek Group (Figure 2). Generally four formations are recognised in the Success Creek Group for a combined thickness

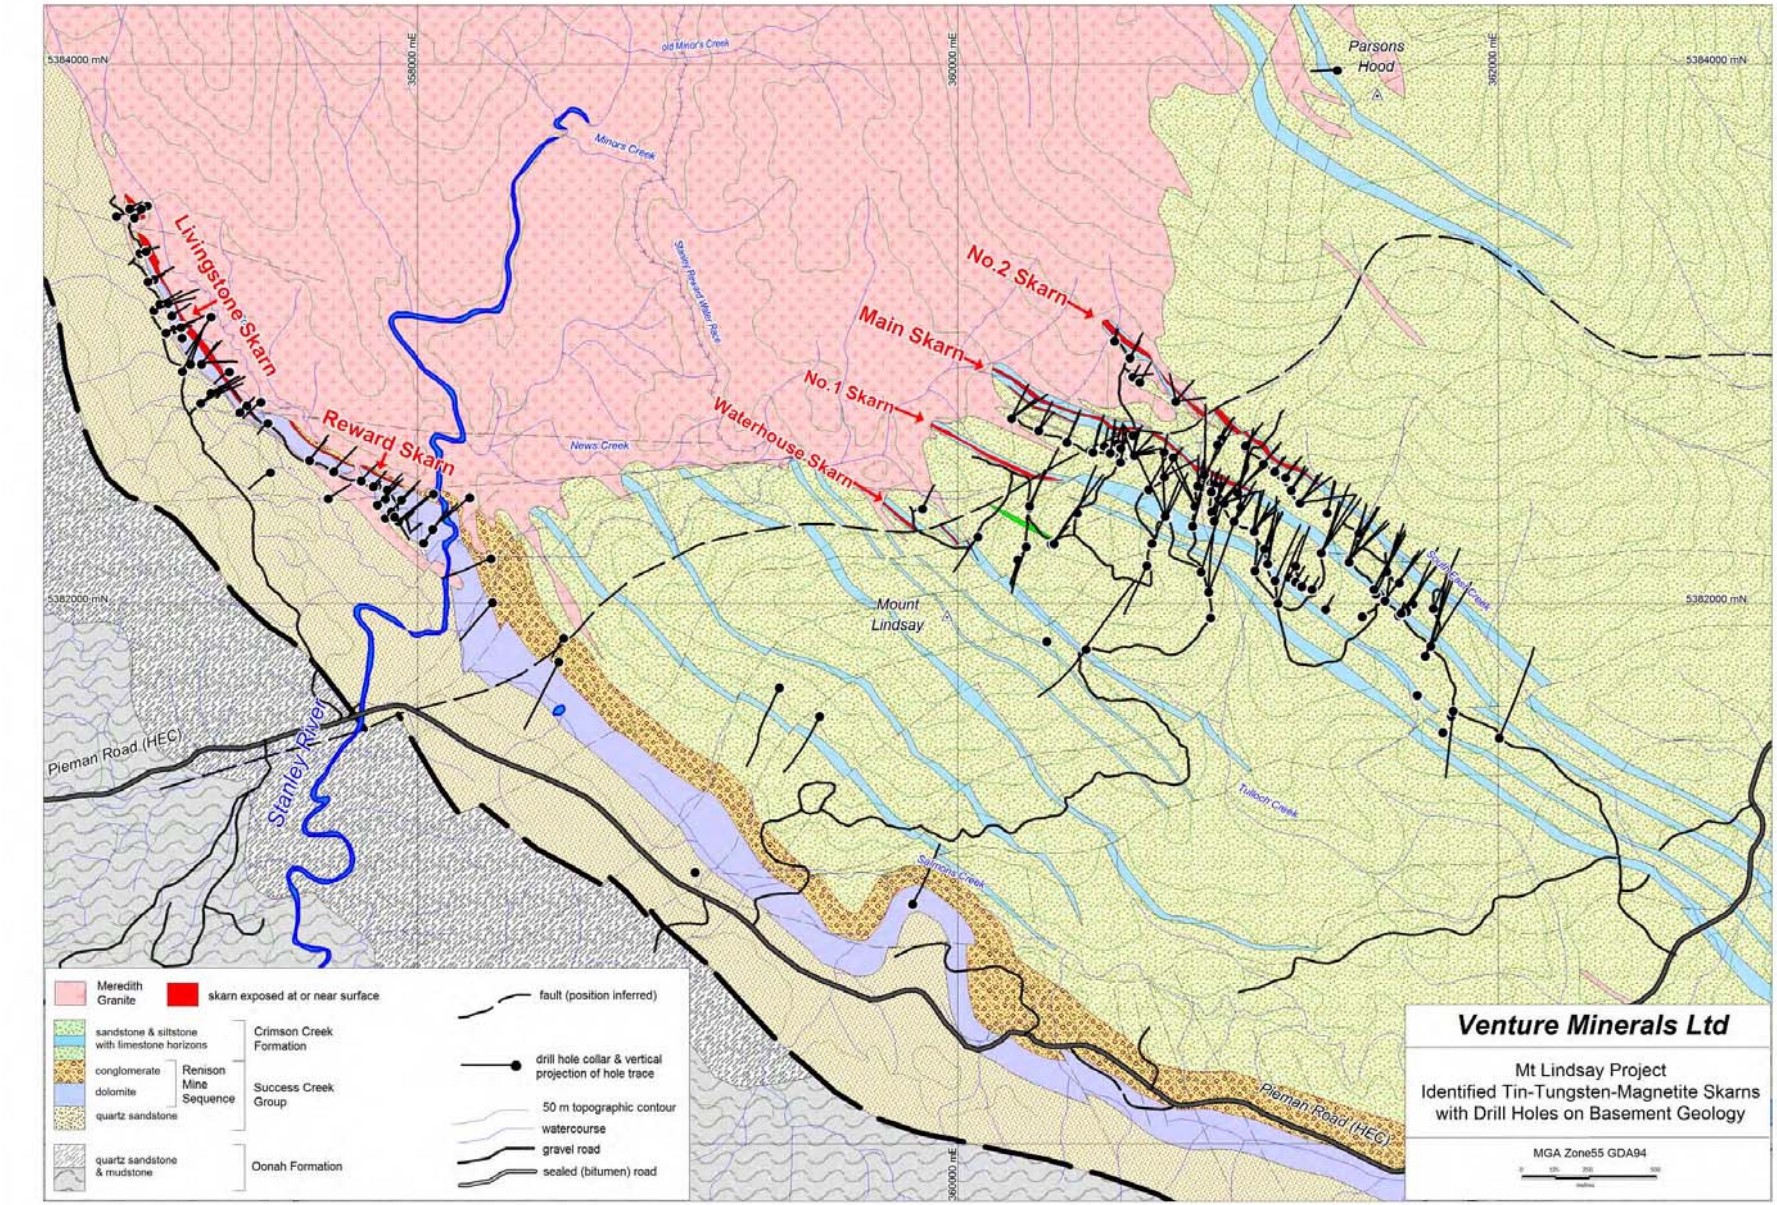

Figure 2: Mt Lindsay Project Geology with Drill Holes

of 950 m: a basal conglomerate with sandstone lenses, overlain by quartz sandstone with minor siltstone and conglomerate (Dalcoath Formation), then black mudstone, siltstone and minor quartz sandstone, and finally siliceous siltstone, red chert and mudstone with minor quartz sandstone, conglomerate and dolomite (Renison Bell Formation). Most of the eastern part of the project area is underlain by the Crimson Creek Formation which reaches c. 5000 m thickness and comprises mainly volcanogenic sandstone and siltstone with scattered laminated felsic tuffites, carbonate horizons and rare tholeiitic basalt. The Meredith Granite underlies the central part of the Mt Lindsay Project area. The margin of the Meredith Granite dips at a modest angle away to south beneath the Success Creek Group and Crimson Creek Formation but is highly irregular in detail with numerous dykes and apophyses stoping the meta-sedimentary units. Large rafts of skarn and hornfels also occur within the margins of the main granite body. Preliminary interpretation suggests several phases of granite intrusion culminating in late stage quartz+tourmaline veining and the localised development of quartz+tourmaline+topaz greisen.

Geological mapping, geophysical surveys and drilling indicate the presence of at least eight magnetite-tin-tungsten skarns in the Mt Lindsay – Stanley River area. Resources are estimated here for three of the identified magnetite-tin-tungsten skarns, namely the Main and No.2 deposits which are hosted by calcareous sandstone horizons within the Crimson Creek Formation, and the Reward deposit within dolomite and conglomerate of the Success Creek Group (Figure 2).

2.2 Mineralisation

The Mt Lindsay – Stanley River magnetite-tin-tungsten deposits are zoned both spatially and temporally on a scale of 10s to 100s of metres approximately perpendicular to the granite margin. The Main and No.2 deposits are largely calcic skarns formed from thin to medium bedded calcareous sandstone and mudstone, while Reward is a magnesian skarn developed from a thick bedded to massive dolomitic protolith. Spatial zonation reflects protolith type and inferred proximity to fluid source, and the protolith control on alteration appears decreases with inferred increasing fluid to rock ratio proximal to the fluid source. Most of the alteration and mineralisation is developed in carbonate protoliths and the mineral grain size typically ranges from c. 1 to 10mm dimension, locally up to c. 50 to 100 mm dimension, and the terms skarn and greisen are applied as appropriate. Alteration and mineralisation within intercalated and peripheral lithic and quartz wackes, siltstone, mudstone and conglomerate horizons is conpsicuously finer with grainsize typically much less than 1 mm. The terms microskarn and microgreisen are applied to such very fine grained metasomatic alteration, and hornfels for fine grained metamorphic rocks which are widespread in the contact auriole of the Meredith Granite. The following major spatial zones are recognised:

- garnet+vesuvianite+pyroxene skarn (limestone protolith)
- olivine skarn (dolomite protolith)
- pyroxene skarn (limestone and dolomite protoliths)
- serpentine skarn (generally dolomite protolith)
- amphibole skarn (generally limestone protolith)
- borate (vonsenite-ludwigite and hulsite) skarn
- prismatic quartz+siderite+k-feldspar+cassiterite skarn or carbonate replacement
- pyrrhotite and pyrite skarn or carbonate replacement

- magnetite+biotite exogreisen
- fluorite+biotite exogreisen
- axinite, pyroxene, amphibole micro-skarns (impure carbonate and siliciclastic protoliths)
- biotite and quartz+pyrrhotite micro-exogreisen (impure carbonate and siliciclastic protoliths)

In the calcic skarns the zoning ranges from proximal garnet, borate, magnetite and annitic biotite alteration through pyrrhotite and amphibole alteration zones to distal quartz+siderite+cassiterite carbonate replacement and phlogopitic biotite alteration. The pyroxene zone is largely restricted to peripheral impure carbonate and siliciclastic protoliths. The Reward and Livingstone magnesian skarns are broadly zoned from proximal olivine, borates, magnetite, through siderite+cassiterite to distal pyroxene alteration.

Temporal zoning is indicated by successive replacement textures, and the following major temporal stages are identified in the Main and No.2 deposits:

(1) Garnet+vesuvianite+pyroxene skarn (calcsilicate stage), mainly metasomatic with some contact metamorphic component. Maybe early scheelite mineralisation but Sn <500 ppm in the calcsilicate skarns.

(2) Prismatic quartz+siderite+cassiterite skarn favouring the core of the host carbonate with minor overlap with calcsilicate stage skarn. Mixture of infill of veins and cavities and replacement mineralisation.

(3) Borate+amphibole+calcite skarn, widely overprints the garnet+vesuvianite+pyroxene stage and possibly the prismatic quartz+carbonate+cassiterite stage.

(4) Biotite+magnetite+pyrrhotite alteration overprints garnet-vesuvianite-pyroxene skarn, quartz-siderite and borate-amphibole stages. Veins suggest some further precipitation of cassiterite, scheelite, quartz and siderite along with chalcopyrite and arsenopyrite.

(5) Fluorite+biotite greisenization of previous stages. Local brecciation and extensive to near complete replacement of previous stages. Followed by as yet poorly defined chlorite and sericite alteration stages.

Partial replacement of zoned quartz, vesuvianite and cassiterite indicates some lower order temporal complexity within the above scheme. The Reward deposit is temporally zoned in a similar way except the early calcsilicate stage is dominated by olivine rather than garnet and vesuvianite.

Petrography and metallurgical testwork indicates the widespread occurrence of cassiterite in the three deposits. Tin is also present in the borates vonsenite-ludwigite and hulsite, and a trace amount of tin is thought to be present in some silicates and oxides. Logging with an ultraviolet lamp, petrography and metallurgical testwork indicates the main tungsten mineral is scheelite. Wolframite has been observed in trace amounts in some metallurgical samples. Venture's exploration and resource definition efforts have focussed on the cassiterite, scheelite and magnetite-rich parts of the skarns.

2.3 Geometry

The Main and No.2 magnetite-tin-tungsten deposits strike east southeast (c. 120° MGA) away from contact with the Meredith Granite and dip ranges from c. 75° NE to 65° SW (overturned). The granite contact and lower margin of mineralisation dips 10 - 40° to the southeast beneath the Main and No.2 skarns, and granite dykes flank the down dip parts so that they form pendulums or keels within the granite. Magnetite, tin and tungsten mineralisation is intermittently exposed at the surface through a thin (typically <1 m) humic regolith for at least 950 m along the Main Skarn and c. 750 m for the No.2 Skarn, then the top of mineralisation plunges to the south east at 20-50° for at least a further 200-1200 m for both deposits. Drilling indicates the plunge of the Main and No.2 skarns steepens towards the southeast. True thickness of magnetite mineralisation in the No.2 Skarn averages 20-25 m and locally reaches up to 35 m. Magnetite and sulphide mineralisation in the Main Skarn is typically c. 15 m true, but thickens to c. 35 m and bifurcates into two 10-15 m thick zones at the western end of the skarn. Tin mineralisation is typically more widespread than magnetite such that the volume of tin mineralised skarn in the Main Skarn is almost double the volume of magnetite mineralised skarn. Calc-silicate and/or sulphide alteration typically extends well beyond the magnetite and tin mineralisation zone in all identified skarns so that total thickness reaches up to c. 80 m. Approximately 150-200 m of hard grey hornfels after siltstone and lithic sandstone separate the Main and No.2 skarns.

Clay zones up to 100 m deep are locally present above and adjacent to the Main and No.2 skarns. Magnetite skarn is relatively resistant to weathering, commonly persisting to surface within clay zones, while sulphide rich skarn has produced gossan. The clay zones are best developed above the down plunge extents of the known skarns and their identification is a useful feature in the exploration for concealed (blind) skarns. Pleistocene erosion has probably removed most of the clay zones over the Main and No.2 skarns on Mt Lindsay exposing fresh skarn at or within a few metres of surface.

The Main and No.2 skarns are cut and offset approx. 55-60 m in a reverse sense by the southeast dipping Tulloch Fault. Several parallel faults of similar geometry are inferred from topographic and geophysical interpretation in the Mt Lindsay area. Drilling and Aberfoyle's mapping of old drives in the adjacent Main Skarn indicates that Tulloch Fault dips 40-60° towards 160° MGA. Tulloch Fault appears to post-date mineralisation and are characterised by several metres of fractured rock with narrow bands of weakly cemented (with rhodocrosite and zeolite) to incoherent breccia and gouge zones scattered over a true thickness of 5-15 m.

The Reward deposit comprises a series of near-vertical lenses which strike and plunge southeast (c. 135-145° MGA) rolling over to dip modestly southwest at the granite contact (contact skarn style). Mineralisation comes to surface at the north western, up-plunge end of the deposit where hematitic gossan is intermittently exposed over a strike extent of c. 150 m. Individual mineralisation lenses at Reward reach up to 10 m thick and are partially to completely weathered to hematite and goethite gossan and ferruginous clays up to a depth of at c. 150 m beneath surface. The adjacent wallrocks (hornfels, sandstone, siltstones and granite) are widely weathered to clay saprolite.

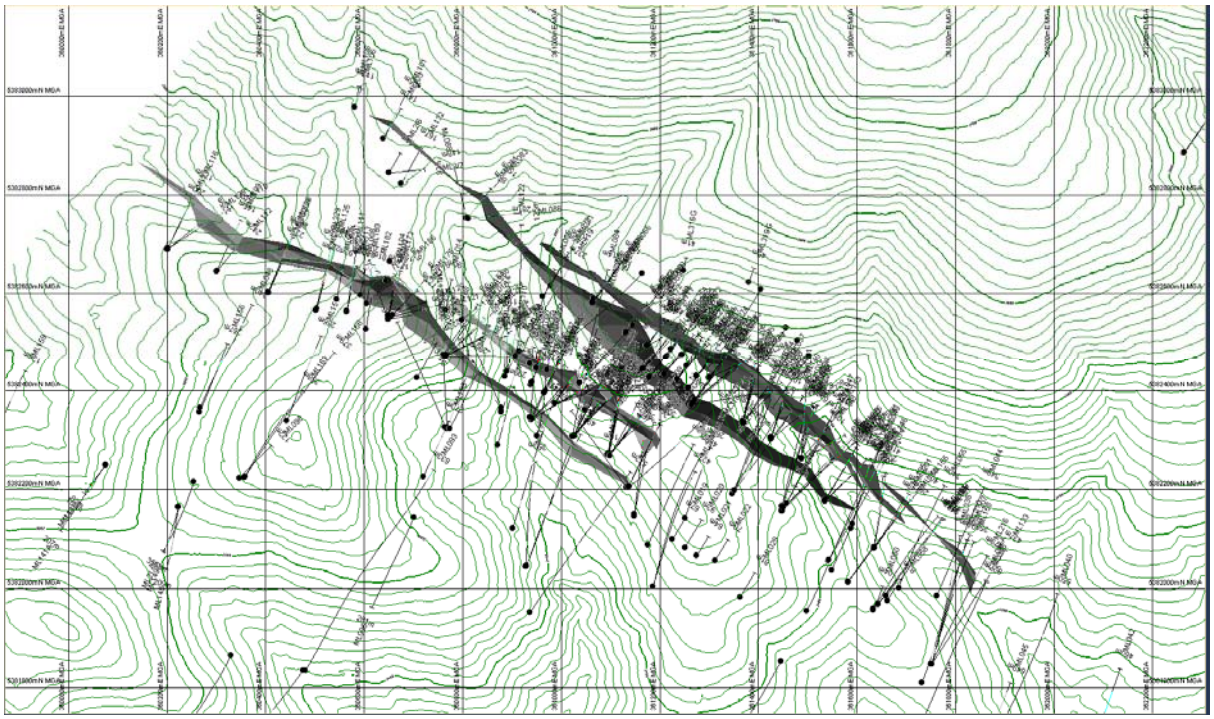

Figure 3: Plan view of Main and No.2 skarns showing drill holes traces (as vertical projections) and the mineralisation wireframes used for the resource estimation (Main Skarn light grey, No.2 Skarn dark grey). The split in each zone is caused by Tulloch Fault, a southeast dipping reverse fault with c. 55-60 m offset. MGA Zone 55 GDA94, 10 m topographic contours.

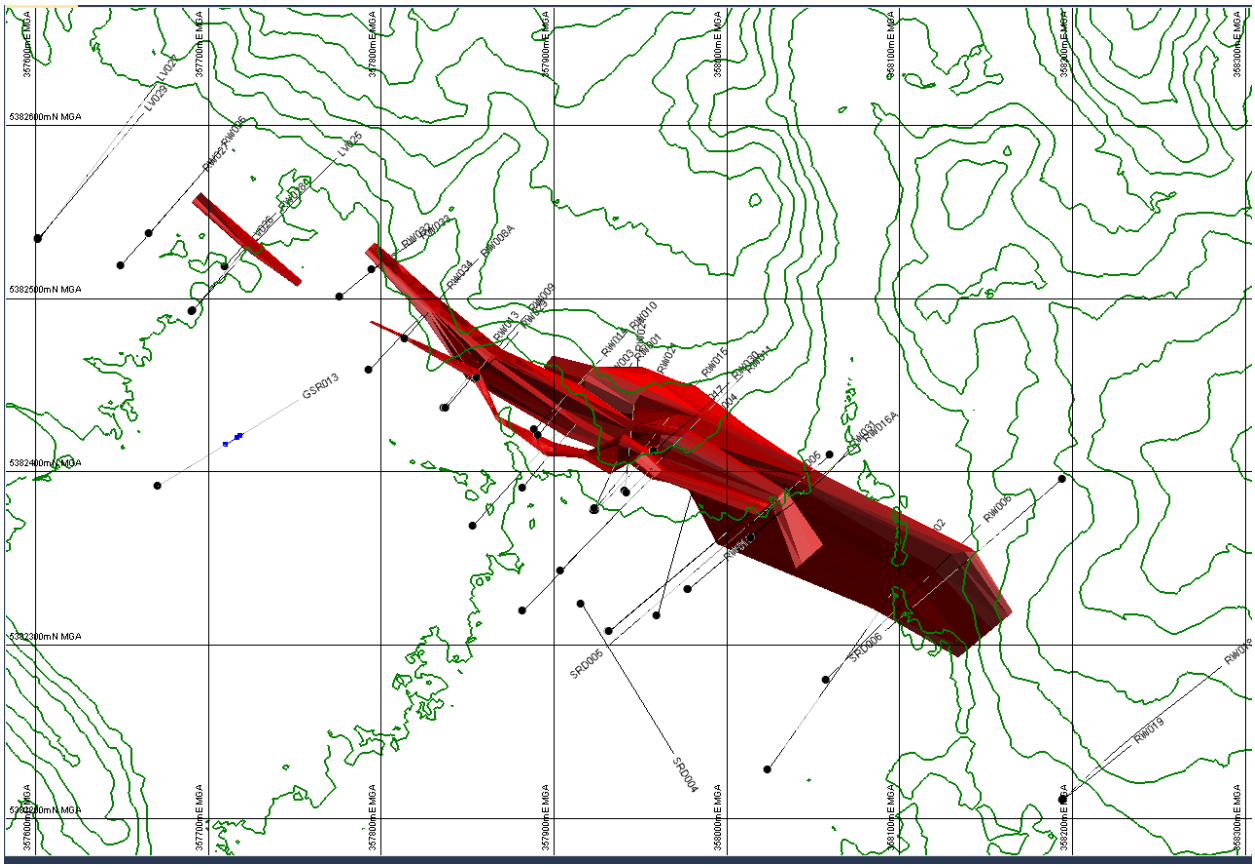

Figure 4: Reward skarn in plan view showing drill holes (as vertical projections) and the mineralisation wireframes used for the resource estimation (in red brown). MGA Zone 55 GDA94, 50 m topographic contours.

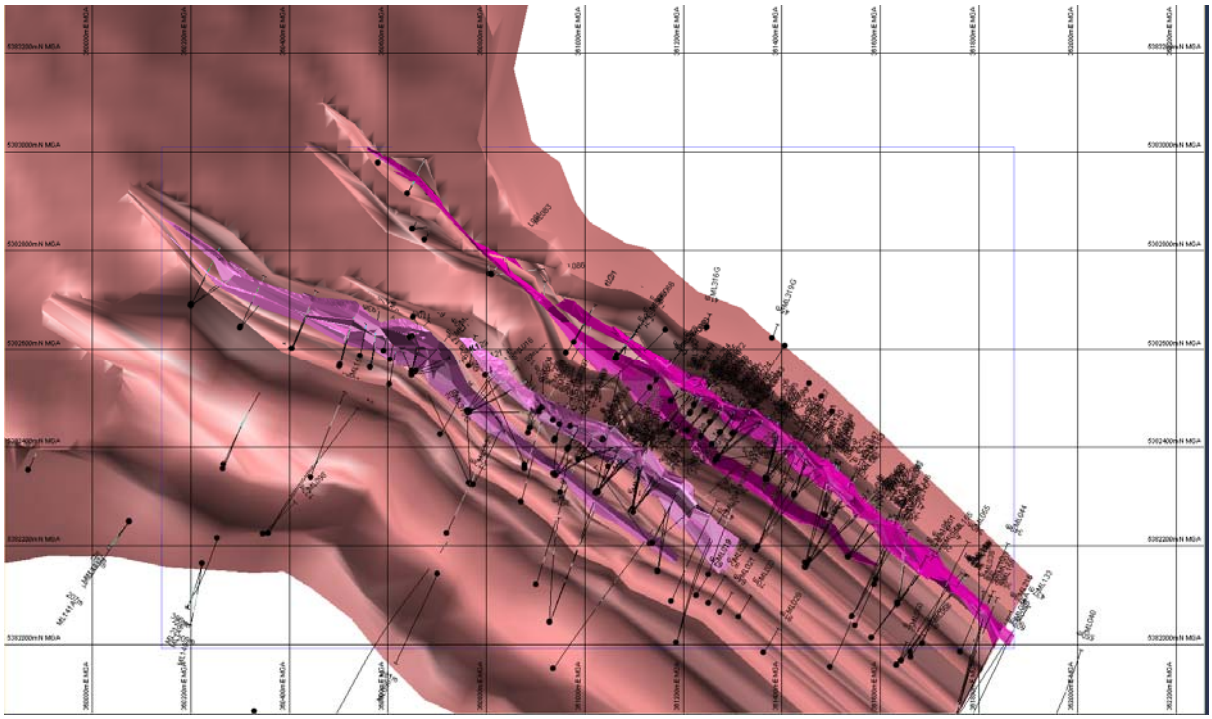

Figure 5: Oblique view looking down (plan) onto Main Skarn (light pink) and No.2 Skarn (dark pink) over a protrusion in the Meredith Granite (rose). The sedimentary rocks hosting the skarns are not shown for clarity. The skarns clearly occupy furrows in the surface of the granite. All drill holes originate from the surface. Tulloch Fault (not shown for clarity) separates the two major parts of the wireframes. North to the top of figure

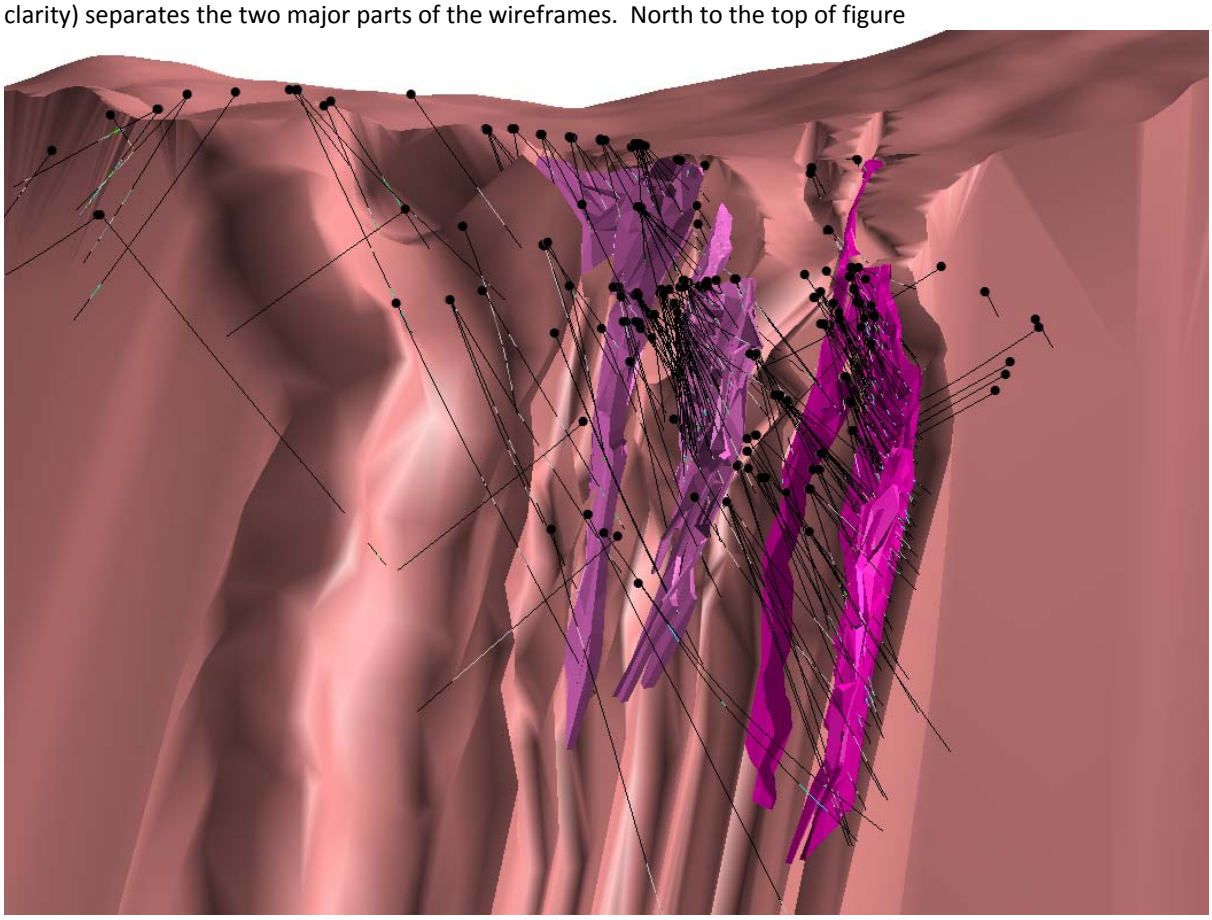

Figure 6: Oblique view towards the north of the Main Skarn (light pink), No.2 Skarn (dark pink) and Meredith Granite (rose). The sedimentary rocks hosting the skarns are not shown for clarity. The skarns clearly occupy furrows in the

surface of the granite. All drill holes originate from the surface. Tulloch Fault (not shown for clarity) separates the two major parts of the wireframes.

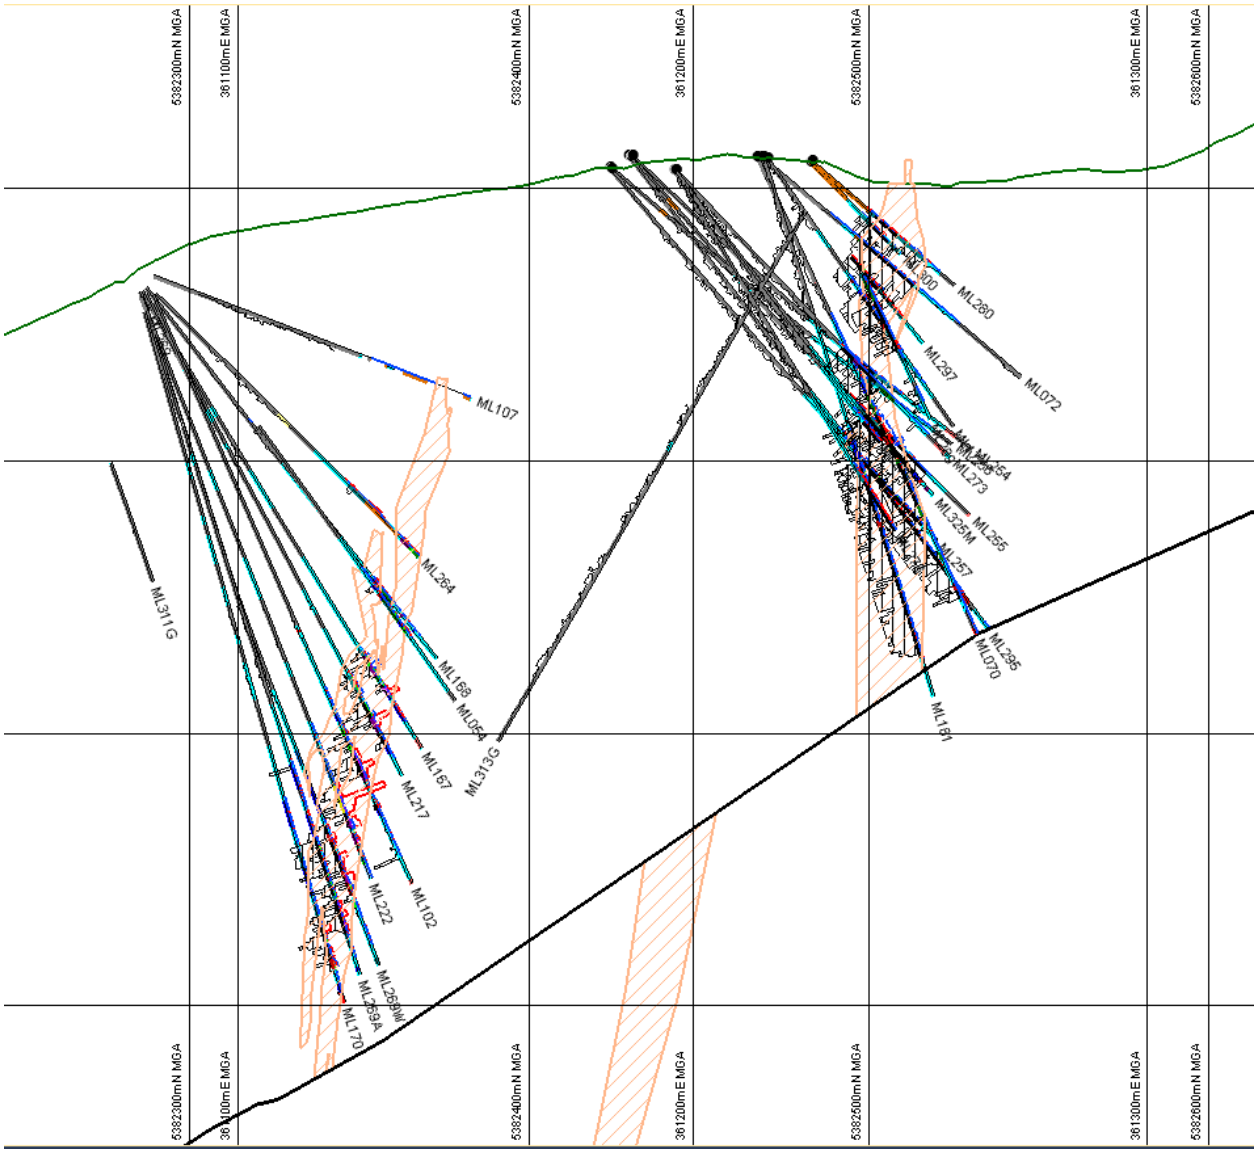

Figure 7: Cross section looking towards MGA NW of the Main Skarn (left) and No.2 Skarn (right) mineralisation wireframes with drill hole traces colored by lithology (pink = granite, grey = sandstone & siltstone, red = fault zone, blue = pyroxene skarn, green = amphibole and magnetite skarn, black = magnetite skarn, magenta = sulphide & biotite skarn, orange = clay). Red graph on right of drill traces Sn %, blue graph on right WO_3 %, black graph on left magnetic susceptibility. Separation of the No.2 Skarn (and Main Skarn off bottom of view) into upper and lower parts is the result of offset on Tulloch Fault. X and Y coordinates MGA Zone 55 GDA94, RL AHD83 + 2000 m.

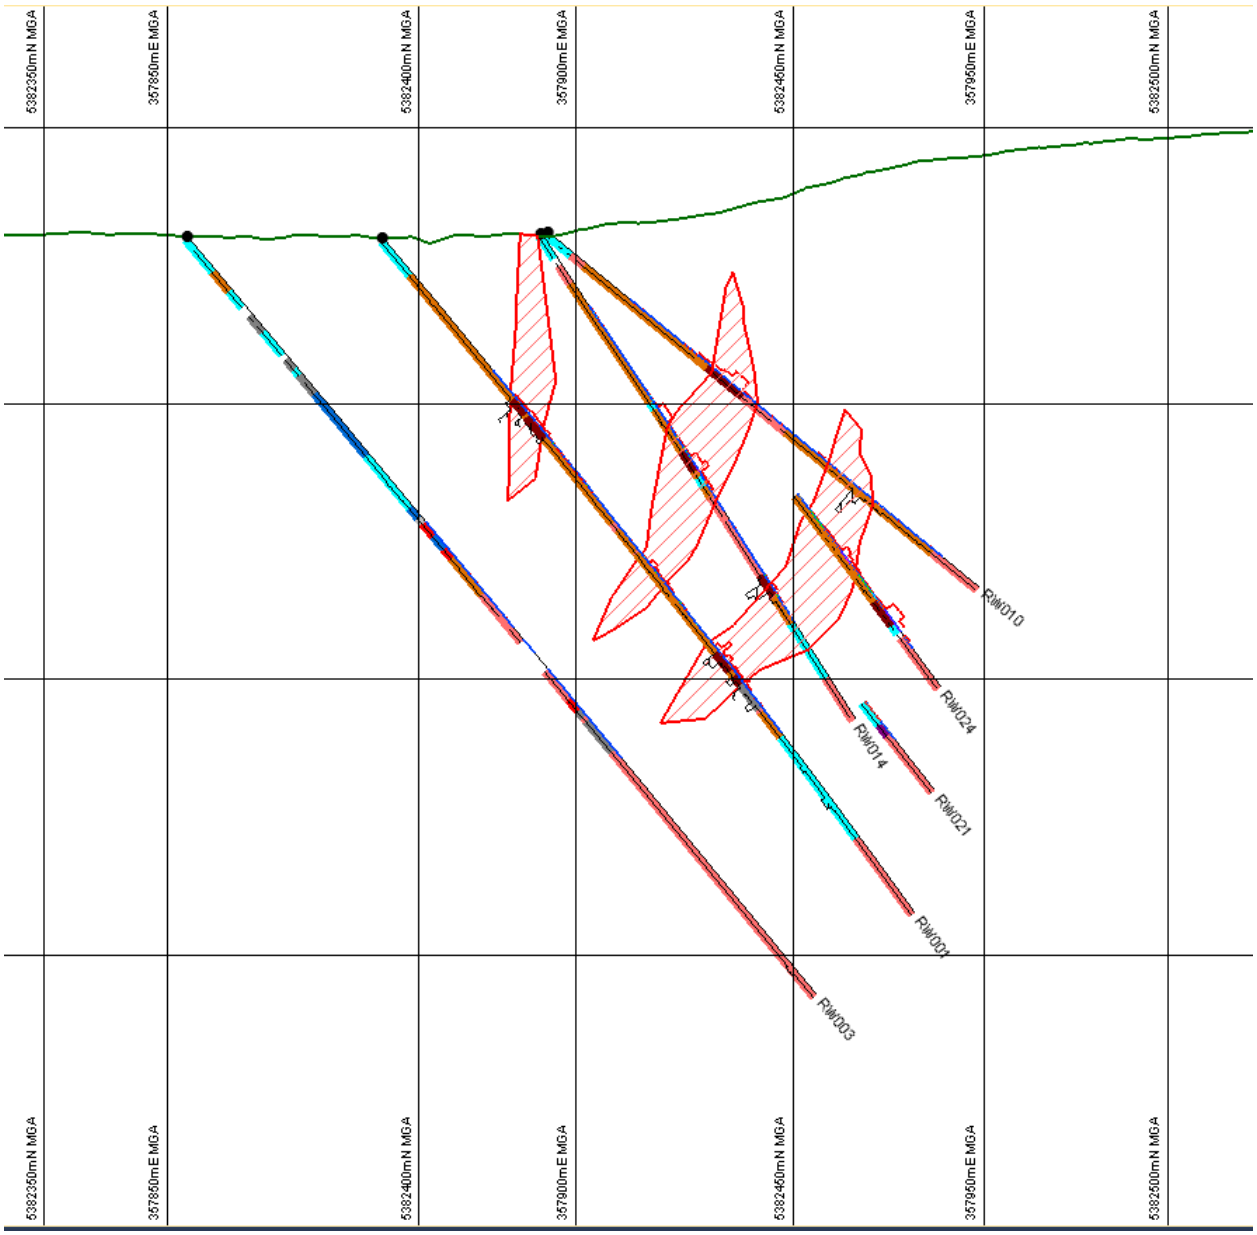

Figure 8: Cross section of the Reward Skarn looking towards MGA NW. Drill hole traces colored by lithology (orange = clay, dark red brown = gossan, pink = granite, grey = sandstone & siltstone, red = breccia zone, pale blue = pyroxene skarn, dark blue = dolomite and marble, green = olivine and serpentine skarn, black = magnetite skarn). Sn & WO_3 left to right on right side of drill traces, Fe % on left. X and Y coordinates MGA Zone 55 GDA94, RL AHD83 + 2000 m.

2.4 Mineralised Intersections

Down hole Sn, WO_3, MR (magnetically recoverable Fe**)** and Cu intersections from within the wireframes used for this resource estimate are listed in Table 2 below. There is a minor amount of mineralisation beyond the wireframes, either low grade or in narrow bands of higher grade material separated from the main body, which is excluded from this resource estimate.

Table 2: Sn & WO_3 intercepts >0.1 % Sn or WO_3 or > 30% MR within (recoverable magnetic Fe) the combined mineralisation wireframes.

3 Previous Resource Estimates

Aberfoyle made several estimates of the tin resources within central part of the Main Skarn at Mt Lindsay in the 1960s, culminating in an estimate of 208,799 tons at 0.832% Sn. The resource does not comply with the JORC guidelines and details of the extent and estimation methodology and parameters are not available.

An Inferred Resource of 20 Mt at 33% Fe was estimated for the No.2 Skarn by Venture in June 2008. This was updated in January 2009 by an Inferred Resources of 30 Mt at 33% Fe, 23 Mt at 0.2% Sn at a 0.1% lower cut off, and 5.7 Mt at 0.3% WO_3 at a 0.1% lower cut off for the Main and No.2 skarns combined. A further update to Inferred Resources for the Main and No.2 skarns was made in March 2010 to 36 Mt at 0.4% Sn equivalent (0.2% Sn, 0.09% WO_3 & 20% magnetic Fe) at a 0.2% Sn equivalent lower cut off. In November 2010 Venture estimated additional resources for the Reward and Livingstone Skarns for the first time. The combined Resource for the Main, No.2, Reward and Livingstone Skarns was 43 Mt at 0.4% Sn Equivalent (0.2% Sn, 0.09% WO_3 and 19% magnetic Fe) at a 0.2% Sn Equivalent cut off.

The updated resource estimate presented here omits the Livingstone Skarn resources, as they are currently treated as a DSO resource.

4 Available Data

4.1 Grid Convention and Survey Control

The grid convention used for Venture's work at Mt Lindsay is MGA Zone 55 GDA94 and AHD83 +2000 m for elevation. Historic exploration and drilling work by CSR, Aberfoyle and Renison was done on a local grid and collars were surveyed using a total station system. Some of the CSR, Renison and Aberfoyle collar pipes were relocated by Venture allowing transformation of the historic local grid plans and collar positions to MGA Zone 55 GDA94 coordinates assisted by aerial photography where necessary.

Of Venture Minerals Limited's 327 drill hole collars some 301 (93%) were surveyed in the MGA Zone 55 GDA94 grid and datum by licensed surveyors using a combination of differential GPS and total station survey systems and the remaining 26 collars (7%) were surveyed using handheld GPS.

4.2 Drill Hole Data

Some 428 diamond core drill holes for a total of 78,556 m were used to define the mineralised zones for this resource estimate, including 49 holes for 11,787m drilled by previous explorers. Of this drilling some 122 holes for 25,582 m pierced the Main Skarn , 134 holes for 27,650 m pierced the No.2 Skarn (note that six holes pierced both skarns), and 20 holes for 2,953 m pierced the Reward Skarn. Of the total 323 drill holes used for the current Resource estimation some 21 holes for 4,761 m core of mainly BQ size (36.5mm

diameter) were drilled by the previous owners Aberfoyle Tin Development Partnership and Renison Limited; the other 302 drill holes for 56,965 m were drilled by Venture Minerals Limited with most of the core used in the resource estimate being HQ size (63.5mm diameter, 51% of samples) and NQ size (47.6mm diameter, 40% of samples). The rest of samples were taken from BQ size core (36.5mm diameter, 7% of samples), PQ size core (85mm diameter, 1% of samples) and less than 1% combined of samples taken from other drill methods (such as AX size core).

Drill hole density in the Main Skarn ranges from approximately 25 m by 10 m to a maximum of c. 120 m, and the No.2 Skarn from approximately 20 m by 10 m to a maximum of c. 120 m. Overall drill hole spacing for both skarns is very approximately 40 m by 25 m.The drill hole density in the Reward Skarn ranges from approximately 25 m by 10 m to a maximum of c. 100 m.

4.3 Downhole Surveys

Some 57% of the previous owners drill holes were surveyed with a down hole camera. Some azimuth measurements were rejected because of interference in magnetic ground, in which case azimuth was interpolated or extrapolated from the nearest acceptable measurement(s). All plunge measurements were accepted.

All of Venture Minerals Limited's drill holes were surveyed with conventional magnetic instruments. All plunge measurements were adopted but only consistent azimuth data were accepted. Some 2% of Venture's drill holes were also surveyed by north-seeking gyroinclinometer tool by independent contractor Northern Exploration Pty Ltd, and some 63% of Venture's drill holes were surveyed by appropriately trained Venture personnel using non-magnetic Deviflex tools hired from DH Surveys Pty Ltd. Only 3% of holes included in the resource estimates received collar orientations only.

4.4 Bulk Densities

The densities used in the resource estimation were based on 7,319 specific gravity measurements made on the diamond core at one metre intervals within the mineralised zones. Density measurements were conducted on a 1 m basis through the fresh mineralised materials and adjacent wall rock by Venture personnel in Venture's Tullah exploration facilities. The fresh drill core was weighed in 1 m intervals dry in air to 1 g accuracy, and then the samples were weighed again suspended in water. The density was calculated using the formula Wtair / (Wtair – Wtwater). In situations where core recoveries are less than 100% or where the core was badly broken (fault zones) pieces of representative core were selected from the single metre intervals and weighed in the same manner. A minimum of 1 kg of rock was selected wherever possible to maximise weighing precision. The density of weathered materials (clay and saprock) were determined by using either callipers (for intact sticks of clay) or volumetric flask (for irregular core sealed with beeswax) to determine core volume and oven dried weight (minimum of 8 hours at 110° C) by 5 kg scales with an accuracy of 1 g.

Fresh rock density for the Main and No.2 Skarns was interpolated to the block model using the same technique as for grade estimation. Weathered materials which account for only c. 2% of the Sn equivalent resource estimate were assigned to a separate domain with an average density 1.7 in the Main and No.2

Skarns. The mean density for the Main Skarn was 3.39 t/m^3, whilst for the No. 2 Skarn it was 3.58 t/m^3. Densities for the Reward Skarn were interpolated to the block model using the same technique as the grade estimation. Average density was 2.21 t/m3 for the Reward Skarn.

4.5 Topographic Control

AAM was engaged by Venture Minerals to conduct a LiDAR survey over the resource area and the Airborne Laser Scanning (ALS) data was acquired from a fixed wing aircraft on April 5th and April 6th 2011. GPS base station support was acquired by Tritech Professional Services using an Optech ALTM Gemini 70 kHz Static RTK system. This allowed an assessment of the accuracy of the ALS data. Reduction of the ALS data proceeded without any significant problems. Laser strikes were classified into ground and non-ground points using a single algorithm across the project area. Manual checking and editing of the data classification further improved the quality of the terrain model. The Datum Projection Geoid Model was GDA94 MGA Zone 55 and Ausgeoid98, and Primary Reference Station WCP1 357205.518, E 5380864.729 N, 268.738 RL. Project specifications and technical processes were designed to achieve vertical data accuracy of 0.30 m and horizontal <0.30 m (1/5500 flying height). Ground definition in vegetated terrain may contain localized areas with systematic errors or outliers which fall outside this accuracy estimate. Laser strikes have been classified into “ground” and “non-ground”, based upon algorithms tailored for major terrain/vegetation combinations existing in the project area. The definition of the ground may be less accurate in isolated pockets of dissimilar terrain/vegetation combinations. Ground data was compared to 231 test points obtained by field survey on clear ground and assumed to be error-free, achieving mean difference of -0.253 m to -0.263 m in the Mt Lindsay-Stanley River area. Final accuracy after removal of mean offset yielded mean differences of -0.003 m to 0.007 m with a standard deviation of 0.059 m to 0.060 m. A constant 2000.000 m was added to the AHD83 Z value of all three dimensional data used in this resource work (termed RL2000).

1:25,000 scale 2D watercourses and water body polygons, transport, infrastructure and cultural features were obtained from from Land Information Services Tasmania (the LIST), a division of the Department of Primary Industries, Water and Environment, Tasmania

5 Sampling Methods and Assaying Quality

5.1 Drill core sampling methods

Only logged mineralised drill core was sampled for assay. The CSR and Aberfoyle drill core (AX and BQ) was variously half or quarter core sampled by a longitudinal splitter, and the Renison drill core (largely BQ) was half core sampled with a core saw. It is not known what sampling interval was used by Aberfoyle as the only available assays are composites of the entire mineralised zone(s) in each hole. CSR assayed in a range of intervals from 0.1 m to 20 m with an average 2.4 m. Renison typically assayed 1 m intervals across the mineralised zone(s).

Venture was able to retrieve from storage and reassay some 4 of 21 CSR, Aberfoyle and Renison drill holes involved in this resource estimate. Venture re-sampled and assayed the Renison core in 2 m intervals to

confirm the original assays which typically included Sn, W, Fe, Cu and As. The Aberfoyle drill holes were only assayed for Sn, Cu and As hence needed to be re-assayed for Fe. Unfortunately not all of the mineralised zones were complete (especially the Aberfoyle and CSR drill holes) because of previous re-sampling and/or core loss in storage. Where only quarter BQ or AX core was left Venture re-sampled the entire remaining core in approximately 6 feet or 2 m intervals according to available core markings. Where half BQ core remained quarter core was sampled by core saw in 2 m intervals, except for ML37 from which all remaining mineralised core was composite sampled for metallurgical testwork.

Fresh Venture drill core (NQ and HQ) was sampled by core saw at Venture's logging and storage shed in Tullah. Weathered core (generally HQ, some NQ) was half core sampled by knife for clay and cold chisel or core saw for saprock. The fresh core was logged and typically marked up in 2 m intervals for sampling continuously across the mineralised zones plus some of the adjacent barren wall rock. Weathered core was typically sampled in intervals corresponding to the drilling contractors run lengths, typically 1.5 m or 3 m.

Approximately 40% of Venture samples used in the current resource were collected by cutting a sliver off the side of the core to give a sample of around 20 % by volume. Several measurements of the cut slivers were taken for every hole to check that the volume of sample collected was acceptably consistent. One duplicate sliver sample was cut within each mineralised zone to evaluate sampling error. Approximately 30% of Venture core samples represent ½ NQ core, c. 25% of samples were ½ HQ core, and the remaining 5% of samples mainly a mixture of ¼ HQ and NQ.

5.2 Sample Preparation and Analytical Procedures

There is no information available on sample preparation and analytical procedures employed by Aberfoyle. It is thought that Renison conducted most or all of their assaying of Mt Lindsay drill core at their on-site laboratory at the Renison Bell tin mine, assaying Sn, W & As by XRF on pressed pellets, Cu, Pb, Zn by AAS (acids used in digestion were not specified), sometimes also soluble Sn (again acids used in digestion not specified). Most of CSR's assays were conducted by Amdel in South Australia, with some by SGS Australia Pty Ltd and ALS Pty Ltd. Sn, W and Mo were assayed by XRF, soluble Sn was determined for a few samples by NH_4I sublimination, and Cu, Pb, Zn and Ag by acid digestion with AAS finish; further details of the various methods used are not available.

The Venture core samples were collected in calico bags labelled with a unique sample number for submission to the assay laboratory. Samples were generally crushed and pulverised by ALS Chemex in Adelaide, then assayed at ALS Chemex in Perth. Priority samples (for quick assay) were sent to SGS laboratory at Renison Bell for preparation and assay for a limited suite of elements (Sn, W, Fe and S, at times also Cu, Pb, As and Zn), then the crushed rejects and pulps were retrieved and sent to ALS Chemex in Perth by Venture personnel for assay of a more extensive element suite. Eight (8) samples of historic (Aberfoyle) drill core were assayed at Ultratrace, Perth as part of the metallurgical testwork programme on the No.2 Skarn.

At the SGS Rension laboratory sample preparation comprised a 6 mm crush followed by 50:50 split to produce "A" and "B" coarse rejects. A c. 100g split was then taken from the "B" coarse reject and

pulverised to p80 <75 microns to produce the analytical pulp. The elements Fe, Sn, W and S, and for selected samples also As, Cu, Pb, and Zn, were determined at by XRF on pressed powder disks. Upon receipt of results Venture personnel retrieved the coarse rejects and pulps from SGS Renison for storage at Venture's Tullah facilities. Pulps were then forwarded on to ALS Chemex, Perth for assay of a more extensive element suite. Splits were also taken of crushed rejects with high magnetic susceptibility and forwarded to ALS Chemex, Perth for Davis Tube Recovery (DTR) and assay (see below) of head and concentrate by XRF fusion.

At ALS the samples are fine crushed to 70% passing 2 mm and split simultaneously through a rotary splitter set by weight to produce subsamples of approx. 100 g for pulverizing. The large -2 mm bulk residue was retained in the original calico bag, and the 100 g split was pulverised using an LM2 machine to 85% passing 75 microns. ALS Chemex then air freighted the pulps to their laboratory in Perth for assay according to the following schemes:

ALS assay scheme 1 (2007 to April 2008): Al, Fe, Mg, Ca, Ti, Na, K, P, S, W, Ag, As, Pb, Sr, Ni, Cr, Cu, & Zn by multi-acid digest including HF with ICP-AES finish; Ce, Sn, Ta, Li, Nb & U by multiacid-digest including HF with ICP-MS finish; selected samples Au by 30g charge fire assay, solvent extraction & AAS finish to 0.001ppm lower detection limit. Overlimit Fe, Sn and W, and samples prospective for Sn in cassiterite were reassayed by XRF fusion.

ALS assay scheme 2 (April 2008 onwards); Al, As, Ba, Ca, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, P, Pb, S, Si, Sn, Ti, U, V, W, Zn plus LOI by XRF fusion; Ag, As, Be, Bi, Cu, Ni, S, Sb, Sn, and W by 4 acid digest including HF with ICPAES finish and any over limit results rerun by ore grade methods; selected samples Au by 30g charge fire assay, solvent extraction & AAS finish to 0.001ppm lower detection limit.

Samples with significant magnetic susceptibility were submitted to ALS Chemex, Perth for Davis Tube Recovery (DTR) and assay of head and concentrate by XRF fusion by the following scheme. The DTR methodology was recommended by iron ore metallurgical and engineering consultants Promet Engineers Pty Ltd.

ALS Chemex DTR procedure: samples crushed to c. 70% passing 2 mm if prepared by ALS Chemex, or c. 70% passing 6 mm if prepared by SGS Renison. Then 150 - 250 g was split for the DTR process as follows.

1) Pulverise 150 g sample for 90 seconds in a ring pulveriser
2) Wet screen the sample at 75 microns and dry the products
3) Record the oversize weights
4) If less than 20g of oversize is produced then a 150g sample must be re-split and pulverised for a shorter time.
5) Dry and regrind the oversize for 4 seconds for every 5 gms of sample oversize
6) Repeat the screening (dry) until less than 5gm is above 75 microns.
7) Filter press total sample, dry and homogenise.
8) Using a 3 decimal place balance, subsample the pulverised product to give a 20g sample for DTR and use the remaining pulp for head grade assay.

This procedure will give a nominal P80 sizing of 75 micron

Davis Tube Recovery method

Pulveriser Bowl 150ml
Stroke Frequency 60/minute
Stroke length – 38mm
Magnetic field strength – 3000 gauss
Tube Angle – 45 degrees
Tube Diameter – 25mm
Water flow rate – 540ml/min
Washing time 15 minutes

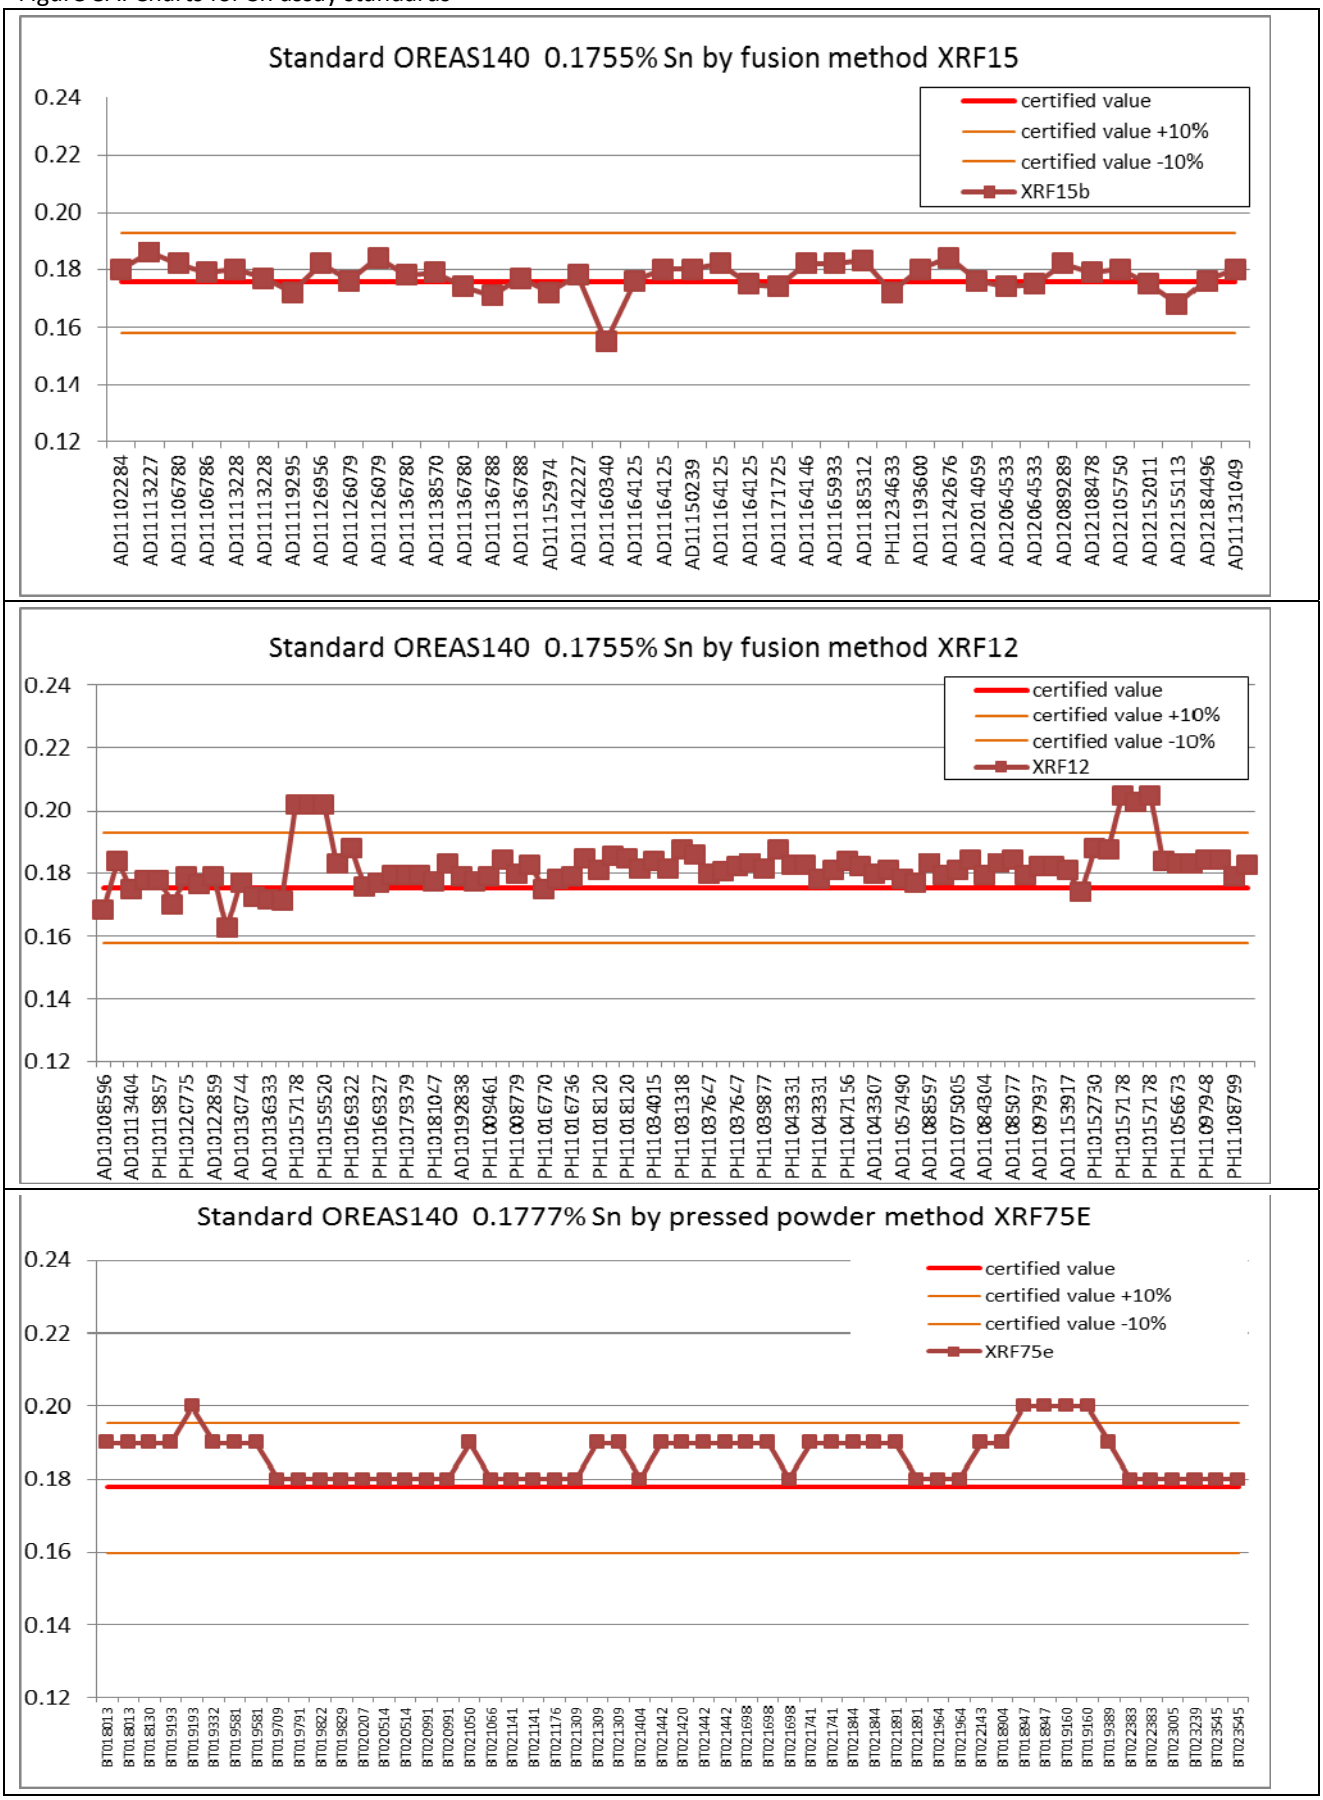
Head subsamples were assayed by XRF fusion for Si, Al, Fe, Mg, Mn, Mo, Ca, Cl, Na, K, Ti, S, Sn, W, P, As, Ba, Co, Cr, Cu, Pb, U, V, Zn and LOI. Selected heads were also assayed B by 3 acid digest with ICP finish, and Ag, As, Be, Bi, Cu, Ni, S, Sb, Sn, and W by 4 acid digest with ICPAES finish and any over limit results rerun by ore grade methods. Davis Tube concentrates were assayed by XRF fusion for Si, Al, Fe, Mg, Mn, Mo, Ca, Cl, Na, K, Ti, S, Sn, W, P, As, Ba, Co, Cr, Cu, Pb, U, V, Zn and LOI.

5.3 Assay Quality Control Procedures and Results

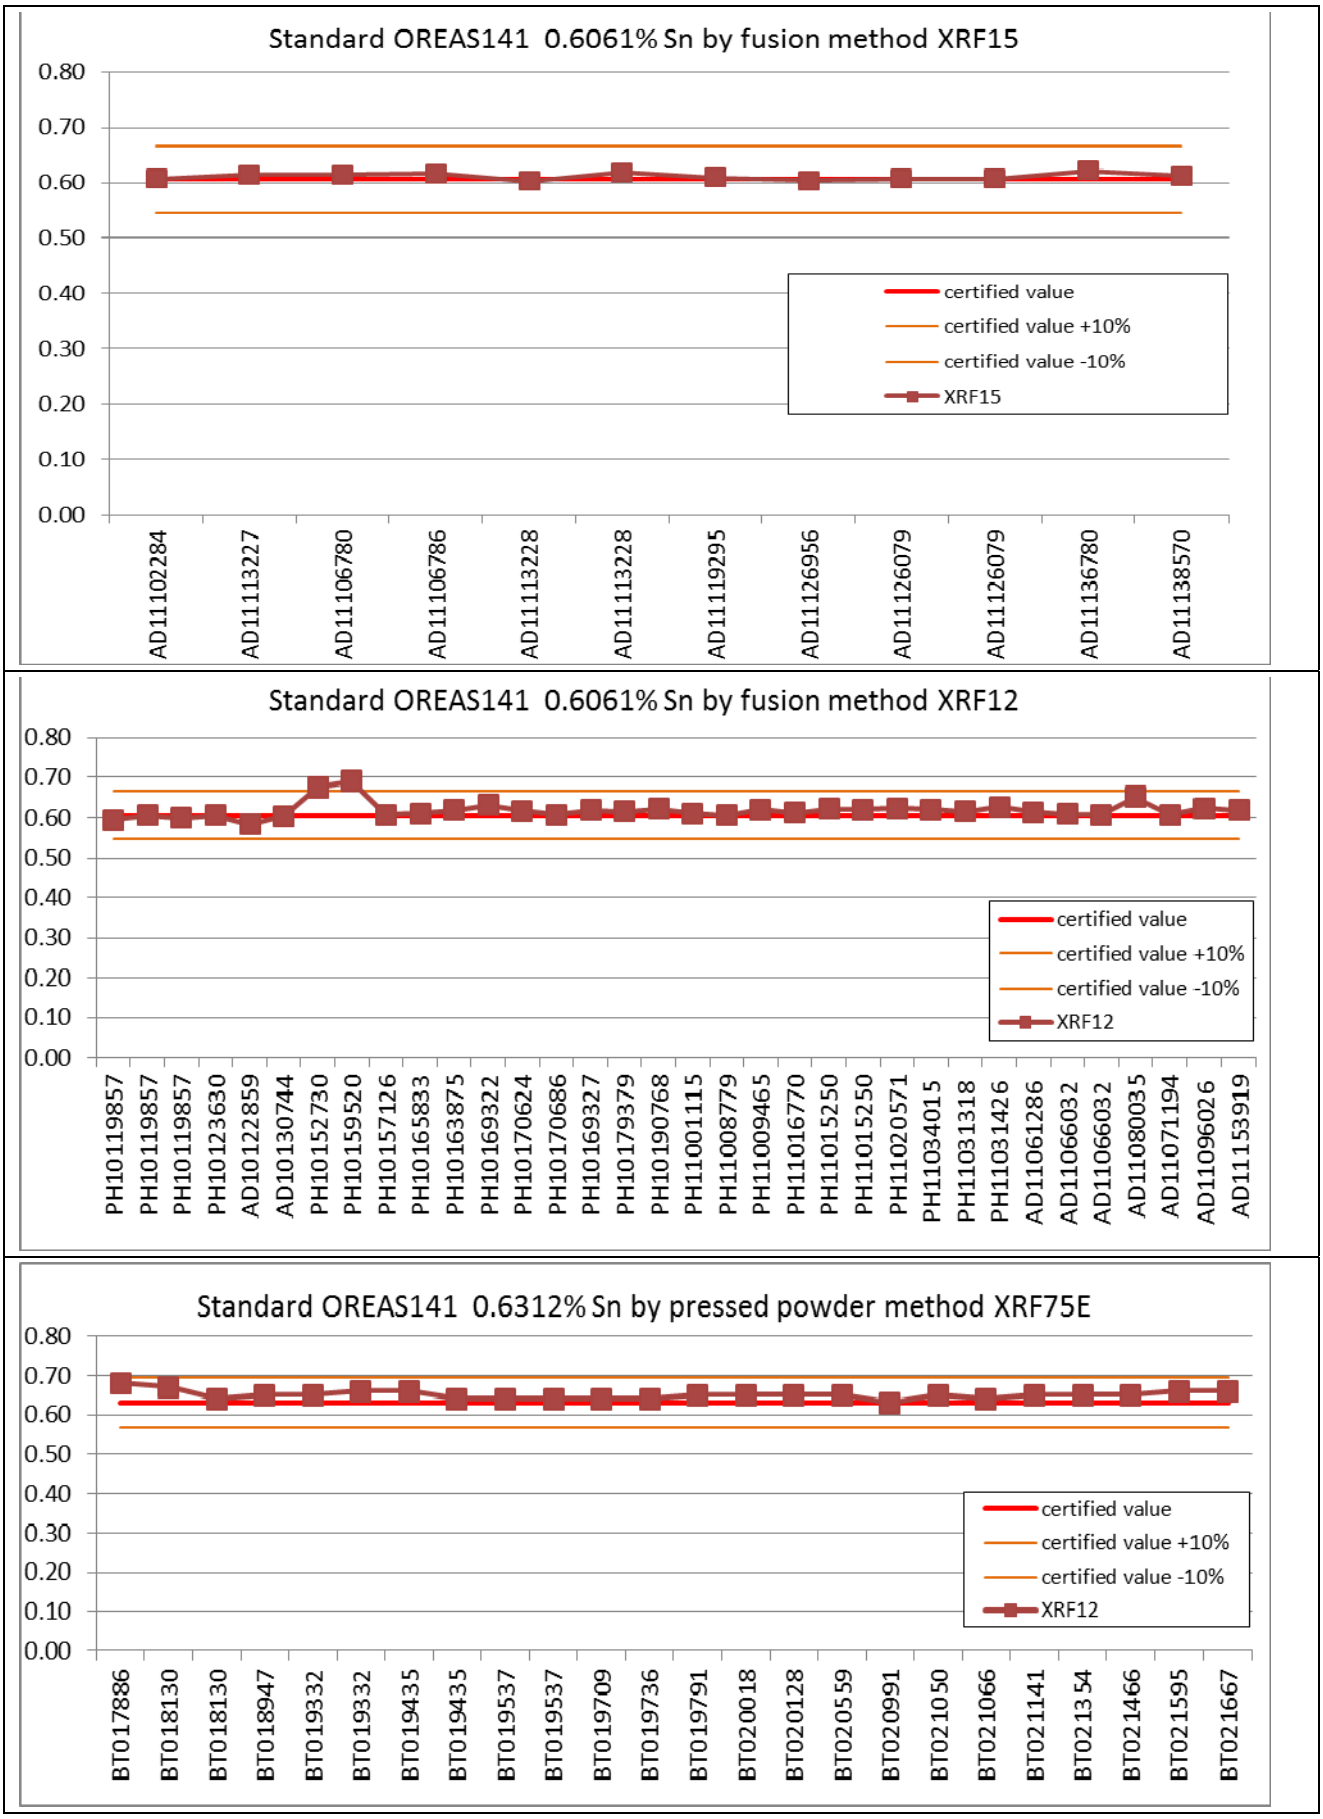
Fe, Sn, W, Cu and DTR standards were inserted at a rate of approximately 1 in every 20 Venture drilling samples. Results for the Sn, W, Cu and Davis Tube Recovery (DTR) standards relevant to the current resource estimate are shown in Figure 8 A to D. The principal assay standards used were certified commercial products purchased in pre-prepared sachets from Ore Research Pty Ltd, Melbourne (standards OREAS140, OREAS141 and OREAS142), Geostats Pty Ltd, Perth (standards GW-01, GW02, GBM306-8 and GBM901-5) and Canada Centre for Mineral and Energy Technology, Ottawa (standard CT-1). Two Sn and Cu standards named MLWL12008 and N2Z2008 were made by Venture personel from pulverised Main and No.2 skarn materials respectively, and three -2mm crushed DTR standards SRL, SRH and MTZP2008 from Savage River low grade, high grade and Main skarn magnetite mineralisation respectively. N2Z2008 is magnetite-rich with minimal sulphides, MLWL12008 is pyrrhotite-rich, and MTZP2008 has moderate magnetite and minor pyrrhotite. SRL and SRH principally comprise magnetite-pyrite-silicate mineralisation. Apprroximately 200-300kg of each standard was crushed, pulverised and homogenised as appropriate for Venture at Burnie Research Laboratory. Reference Sn, W, Cu and S values for N2Z2008 and MLWL12008 were certified through round-robin assaying by Ore Research Pty Ltd. Reference magnetic recoveries using Venture's standard preparation routine (section 5.2 above) where established for the SRH and SRL DTR standards by SGS Lakefield Oretest Pty Ltd, Perth. The Venture standards were stored in sacks in the core shed in Tullah.

XRF is the preferred scheme to obtain total Sn and WO_3 because cassiterite, scheelite and wolframite are generally incompletely soluble to largely insoluble in acids. ALS Global assay methods XRF12 and XRF15 are both fusion X-Ray Fluoresence methods whereby pulverised sample is mixed with a flux and various oxidising agents to produce a glass disk which is then analysed by XRF spectrometry. For XRF12 0.66 g of pulverised sample is fused with a 12:22 lithium metaborate – lithium tetraborate flux and lithium nitrate

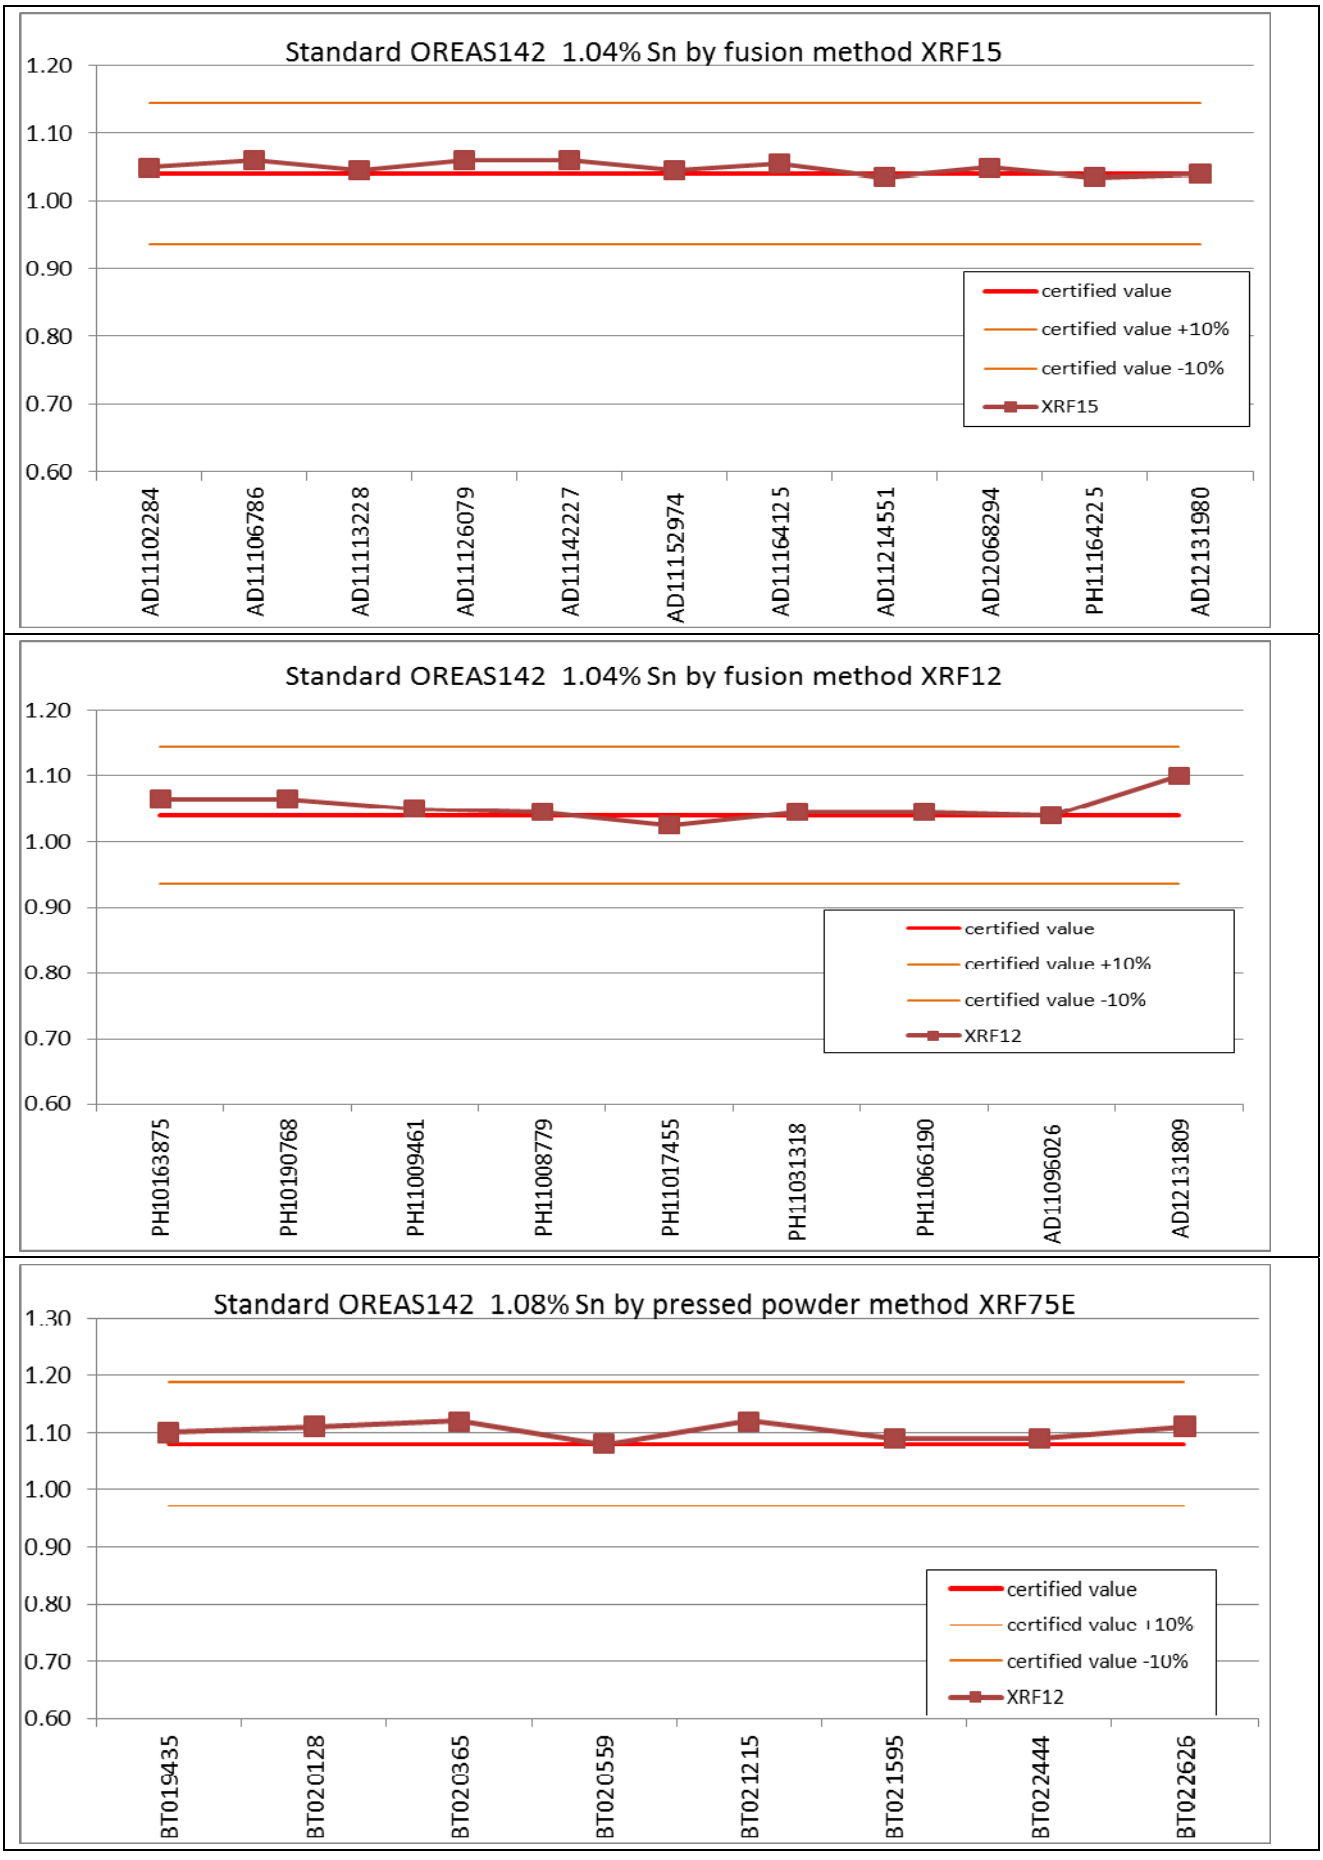
oxidising agent to produce a glass disk, and method XRF15 0.66 g of pulverised sample is fused using a 12:22 lithium metaborate - lithium tetraborate flux containing 20% $NaNO_3$. XRF12 was performed at ALS Perth laboratory, XRF15 at ALS Brisbane facility. SGS method XRF75E is conducted at their Renison Mine laboratory on a pressed powder disks made from the pulverised samples. ALS Global method ICP61 entails digestion of 0.25 g of pulverised sample in a progressive mixture of perchloric, nitric, hydrofluoric and hydrochloric acids, the resulting solution is analyzed by inductively coupled plasma-atomic emission spectrometry (ICP) and results corrected for spectral interelement interferences. Four acid digestions may not dissolve all minerals depending on the sample matrix, and not all elements are quantitatively extracted.



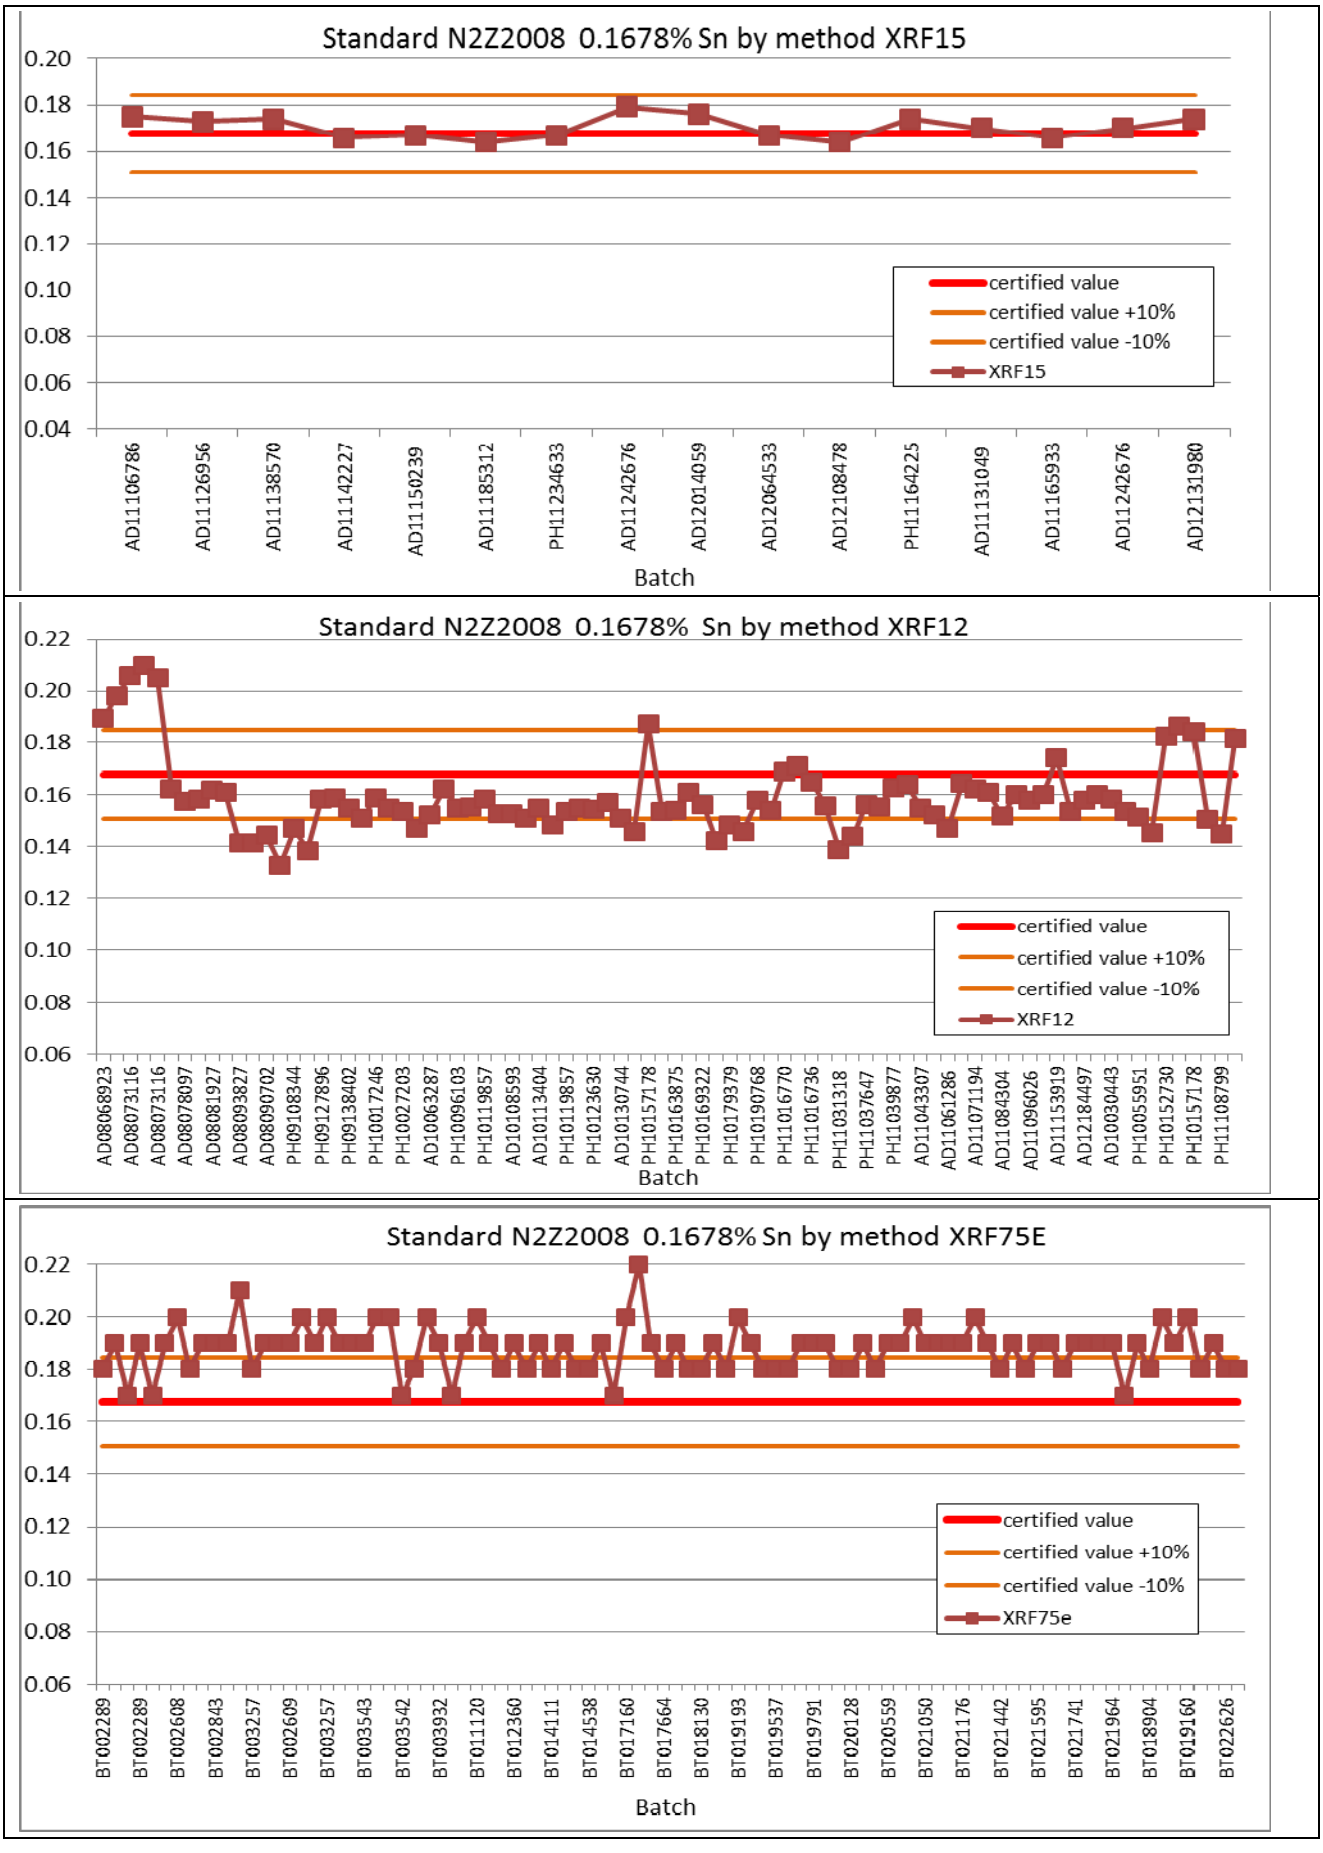
Results for the various standards are presented in Figures 8A (Sn standards), 8B (W standards), 8C (Cu standards) and 8D (DTR standards). The commercial standards were selected to cover the bulk of the grade range encountered at Mt Lindsay. Note that slightly different certified Sn values are quoted by Ore Research Pty Ltd for standards OREAS140, OREAS141 and OREAS142 according to whether the XRF method is by fusion or pressed powders, as refelected in the charts in Figure 8A. Results for the commercial standards are obviously more consistent than for the Venture standards MLWL12008 and N2Z2008. The "noisier" results for the Venture standards suggests homogenisation of the pulverised materials could have been better, and decomposition of sulphide (pyrrhotite) during storage proved a problem with the MLWL12008 standard in particular (leading to clumping and sulphate production). Nevertheless the MLWL12008 and N2Z2008 standards successfully identified inadequacies with the various assay methods (chiefly an undercall by ALS method XRF12) and led to selection of a more appropriate flux for Mt Lindsay type mineralisation (ALS method XRF15).



Method XRF75E was found to return positive bias for the 0.1-0.2% level Sn standards OREAS140 and N2Z2008, and negative bias for W standards GW-01 (0.363% WO_3) and CT-1 (1.31% WO_3). For this reason XRF75E was largely replaced by fusion method XRF12. Unfortunately a slight positive bias appeared for low-level Sn standard OREAS140 (0.18% Sn) and conversely a distinct negative bias for N2Z2008 (0.17% Sn) by method XRF12, so fluxing was reviewed and method XRF12 replaced by XRF15. After a programme of re-assaying (targetting critical grade ranges and samples with high sulphide and magnetite contents) approximately 40% of the Sn and W assays used in this resource estimate were by XRF15, 52% by XRF12 and 8% by XRF75E.



ALS method ICP61 was selected as the prefered scheme for Cu assays used in this resource estimate because none of the XRF methods provided reasonable results at the sub 1000 ppm level (too close to the lower analytical limits, Figure 8C). Slight negative bias was also evident for Cu in MLWL12008 by XRF12 (probably reflecting fluxing issues which appear to have been resolved by the move to XRF15).



Mass Recoveries by ALS for DTR standards SRL (33.5% MR) and SRH (64.5% MR) all fall within 10% of the reference values established by SGS Lakefield Oretest Pty Ltd, Perth. Results for MTZP2008 are somewhat noisier largely falling within 15% of the mean value, possibly reflecting more complex mineralogy of the Mt Lindsay material.

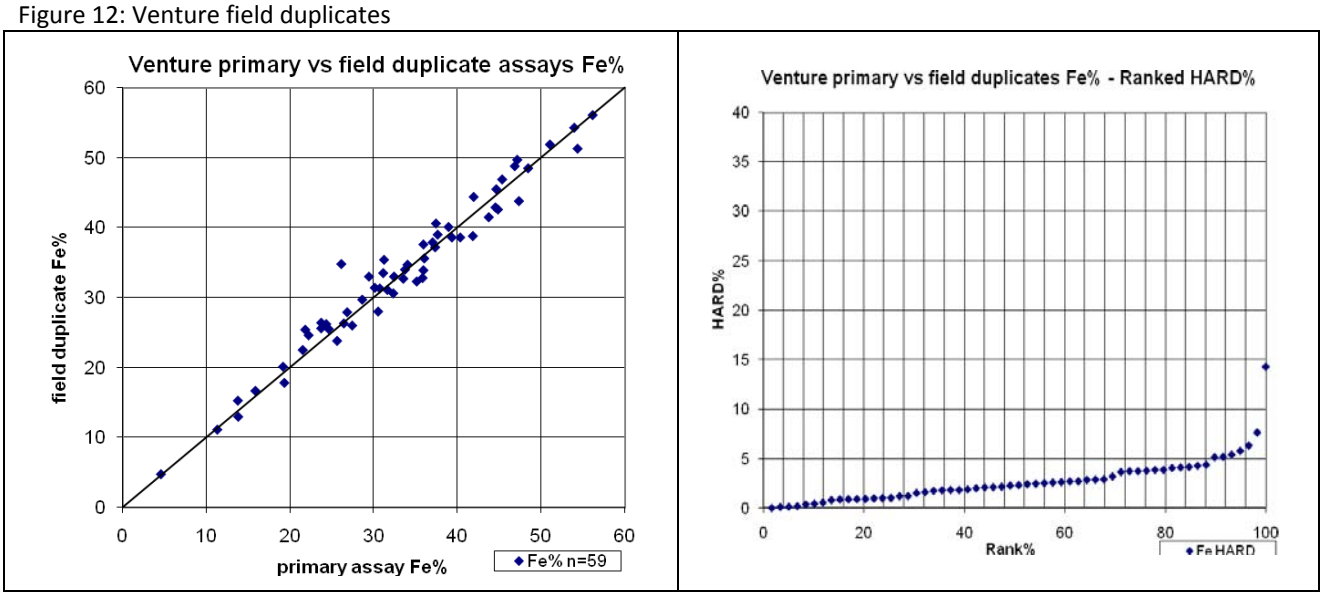

Figure 11D: Charts for Davis Tube Recovery standards

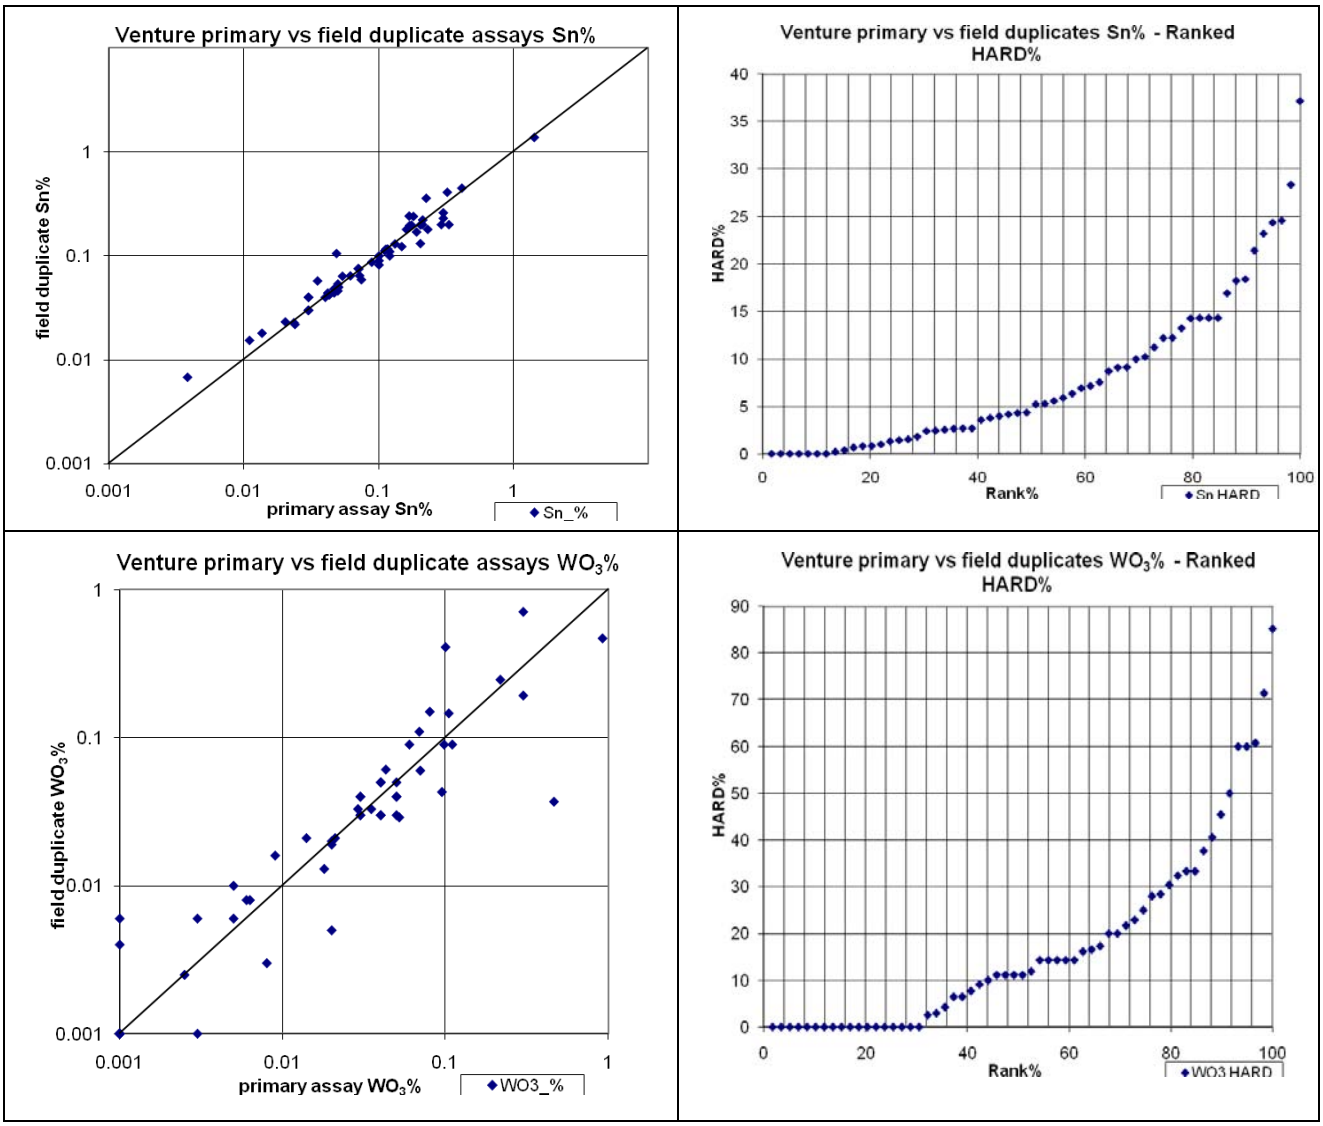
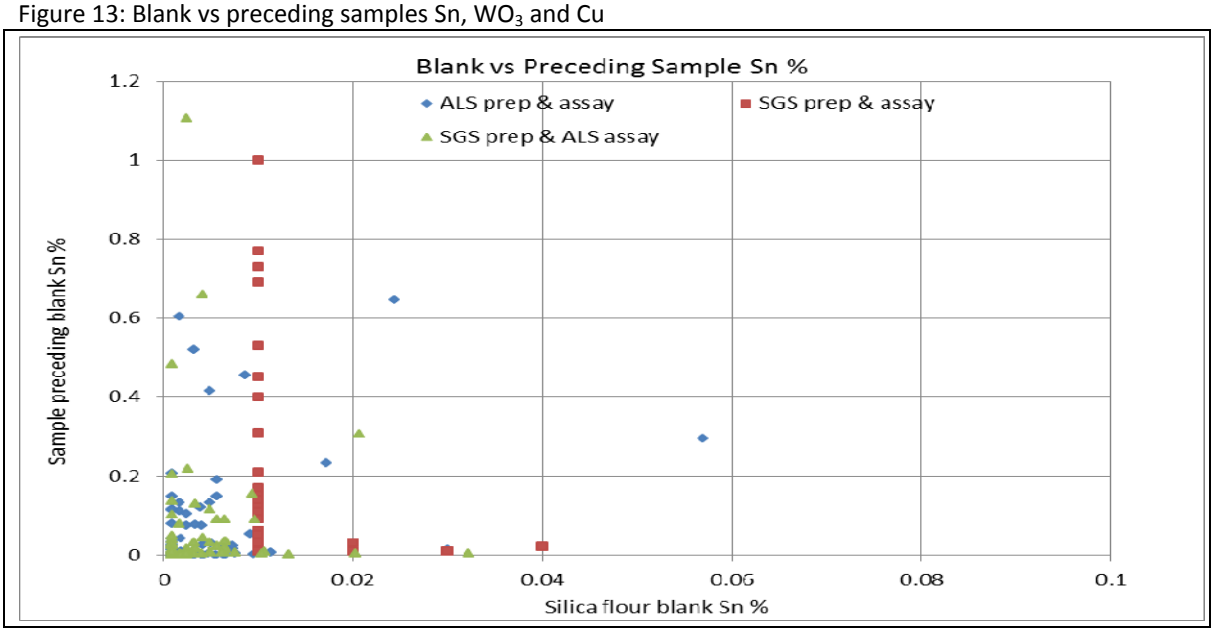
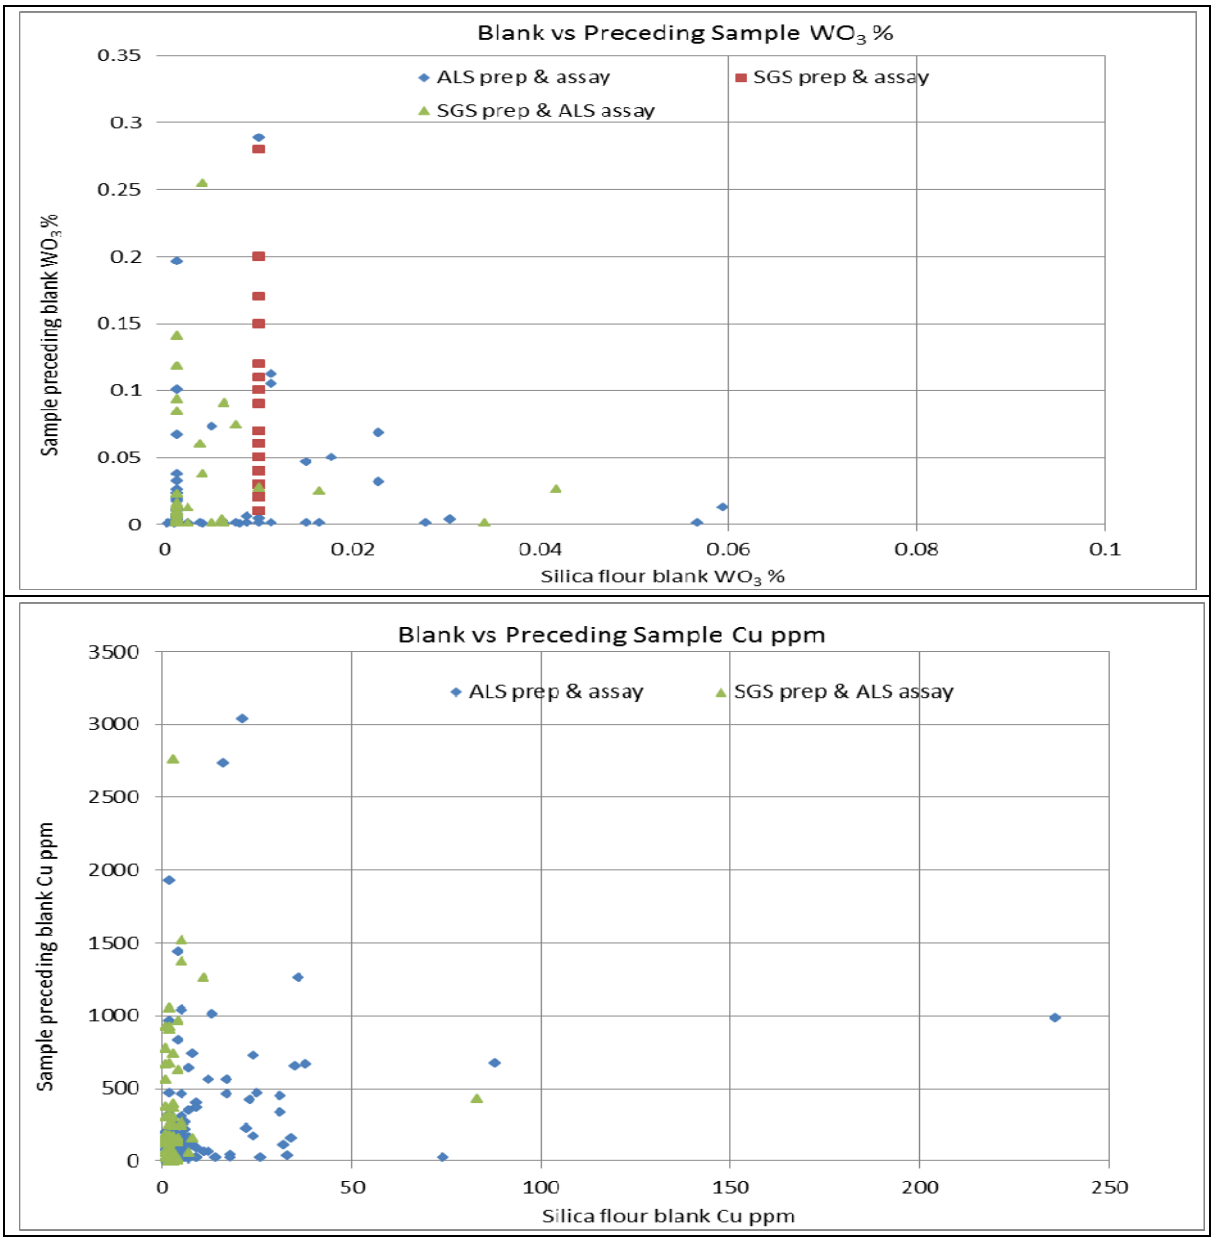
Field duplicates comprised a second sample of mineralised core taken using the same sampling method as the primary sample. The duplicate sample was assigned the sample number subsequent to the primary sample and was submitted in the same batch as the primary sample. The 59 field duplicates allow evaluation of sampling error and, as shown by Figure 9, indicate low sampling variance for Fe and increasing nugget effect for Sn and WO_3. The greater nugget effect for Sn is expected to reflect the particulate nature of cassiterite, and the high sampling variance for WO_3 is expected given the commonly coarse occurrence of scheelite in the Main and No.2 skarns. (Figure 12)

Venture also inserted blanks at a rate of c. 1 per 20 samples to track inter-sample contamination during sample preparation. The blanks comprised 200-1000g of partially indurated silica flour from the local Corinna silica mine. Carry over contamination did not exceed 0.1% for Sn or WO_3 and 250 ppm for Cu at either laboratory. Median and mean Sn and WO_3 carry over contamination for samples both prepared and assayed at SGS Renison was less than the 0.01 % Lower Limit of Detection (LLD). For samples prepared at SGS Renison and assayed at ALS Perth the mean and median carry over for Sn was 45 ppm and 31 ppm respectively, for WO_3 37 ppm and 13 ppm (= LLD) respectively, and Cu 4 ppm and 2 ppm respectively. Samples prepared at ALS Adelaide and assayed at ALS Perth had a mean and median carry over of 33 ppm and 8 ppm (= LLD) respectively for Sn, 51 ppm and 13 ppm (= LLD) respectively for WO_3, and 15 ppm and 7 ppm respectively for Cu. Correlation between Sn, WO_3 or Cu grade of the blank and preceding sample is not observed (Figure 13). The mean carry overs are two orders of magnitude less than the c. 0.1 % Sn or WO_3 cut off used to delineate the mineralised zones for this resource estimate.

Figure 12: Venture field duplicates







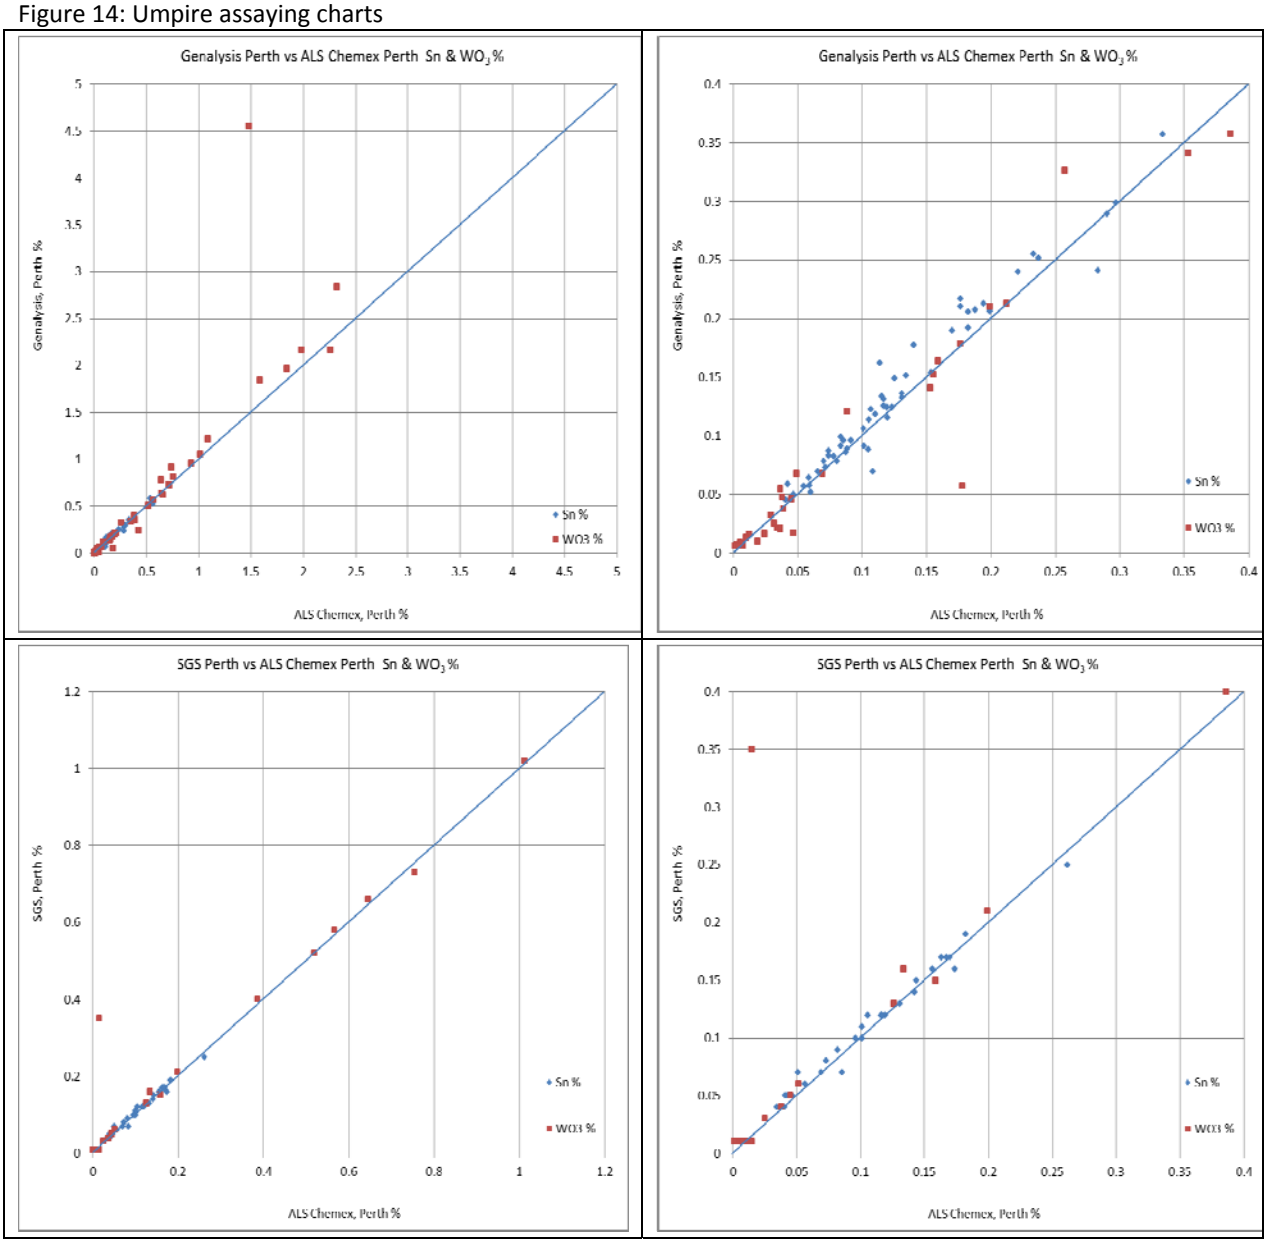


Figure 13: Blank vs preceding samples Sn, WO_3 and Cu

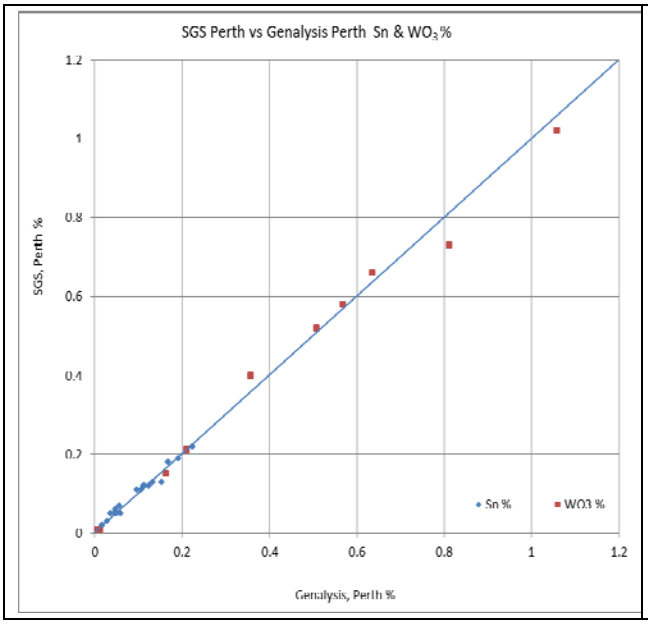

Pulps and residues of 75 mineralised samples were retrieved from storage with ALS Chemex and submitted to SGS, Perth and Genalysis Laboratory Services, Perth and for umpire assaying by XRF on fused beads. Results are shown on Figure 14. Sn results from both SGS and Genalysis have slight positive bias compared with ALS Chemex assays. Significant bias is not evident between SGS and Genalysis samplings lending weight to the above observation that while ALS Chemex performance with XRF on fused beads on commercial Sn and WO_3 standards has been satisfactory there may be slight to modest under-reporting of Sn and WO_3 for the magnetite and sulphide rich matrices encountered within the Mt Lindsay skarns.

Figure 14: Umpire assaying charts

6 Potential for Economic Exploitation

6.1 Potential Mining Scenarios

Open Pit and underground mine designs were completed for the Bankable Feasibility Study where a more detailed description of the work can be found. Ore will be mined from an open pit by contractors and transported to the run of mine stockpile. Conventional open pit mining methods will be used for the near surface material and underground mining for deeper sections of the ore zones. Pits have been designed using Whittle optimisation program and Mine 2-4D software and based on a preliminary geotechnical study which shows generally good ground conditions. Underground designs have been based on a long hole stoping mining method without secondary pillar recovery. Conventional open pit mining equipment will be used including 75-100 tonne trucks and 20-25 cubic metre capacity excavators. Operations will be conducted 24 hours per day, 7 days per week. Waste dumps will be established adjacent to open pits and may be back filled where possible. Underground operations will be accessed from within the open pit by a decline and level development established where required. Ventilation will be through the decline and dedicated ventilation rises. All underground equipment will be trackless and mining will likely be done by a contractor as it is proposed to be at the end of the mine life. Preliminary mine schedules have been completed to define waste removal requirements to achieve the required ore production from the open pits and development requirements for underground mining.

6.2 Metallurgical Testing

A detailed metallurgical testing program has been completed over a five year period to determine the most appropriate methods to extract the valuable minerals of containing tin, tungsten, magnetite and copper from the ore. This has led to the development of a process flow sheet based on the data obtained using proven extraction methods from processing plants around the world. Davis Tube Recovery tests were used to determine magnetite recoveries, gravity and flotation tests for tin and tungsten recoveries and flotation

tests for copper recovery. Preliminary Test work to produce an Ammonium Para- Tungstate (APT) secondary product from tungsten concentrates has been completed. All test work showed acceptable recoveries to saleable concentrate grades. However, final concentrate grades will be determined in forthcoming tests.

6.3 Ore Processing

The process plant has been designed to treat ores from both skarns either together or separately to produce tin concentrate, APT with an option to produce tungsten concentrate, magnetite concentrate and copper concentrate. The plant consists of crushing and grinding circuits, magnetite concentration, copper and a bulk sulphide flotation circuit, tin gravity and flotation circuits, and scheelite flotation followed by an APT circuit. A plant size of 1.75Mtpa has been selected to treat ore over an 9 year period.

The crushing circuit will reduce run of mine ore to P80 of -20mm using primary and secondary crushers and one screen, from which it will be conveyed to a crushed ore stockpile. Ore will then be fed to grinding circuit with a primary rod mill and a primary ball mill that will operate in conjunction with Derrick Screens to achieve a primary grind of p80 ~120 microns. Following grinding circuit ore will pass through a LIMS circuit to separate the magnetite and pyrrhotite from the remainder of the ore. The magnetic fraction will then go to the magnetite circuit while non mags will go to the copper and sulphide flotation circuit. Cassiterite will then be separated from the scheelite by a combination of flotation and gravity, with the cassiterite going into the tin circuit and the scheelite going into then the tungsten circuit. Each circuit will produce a filtered concentrate which will be stored ready for transport. Figure 15 shows a block diagram of the processing route.

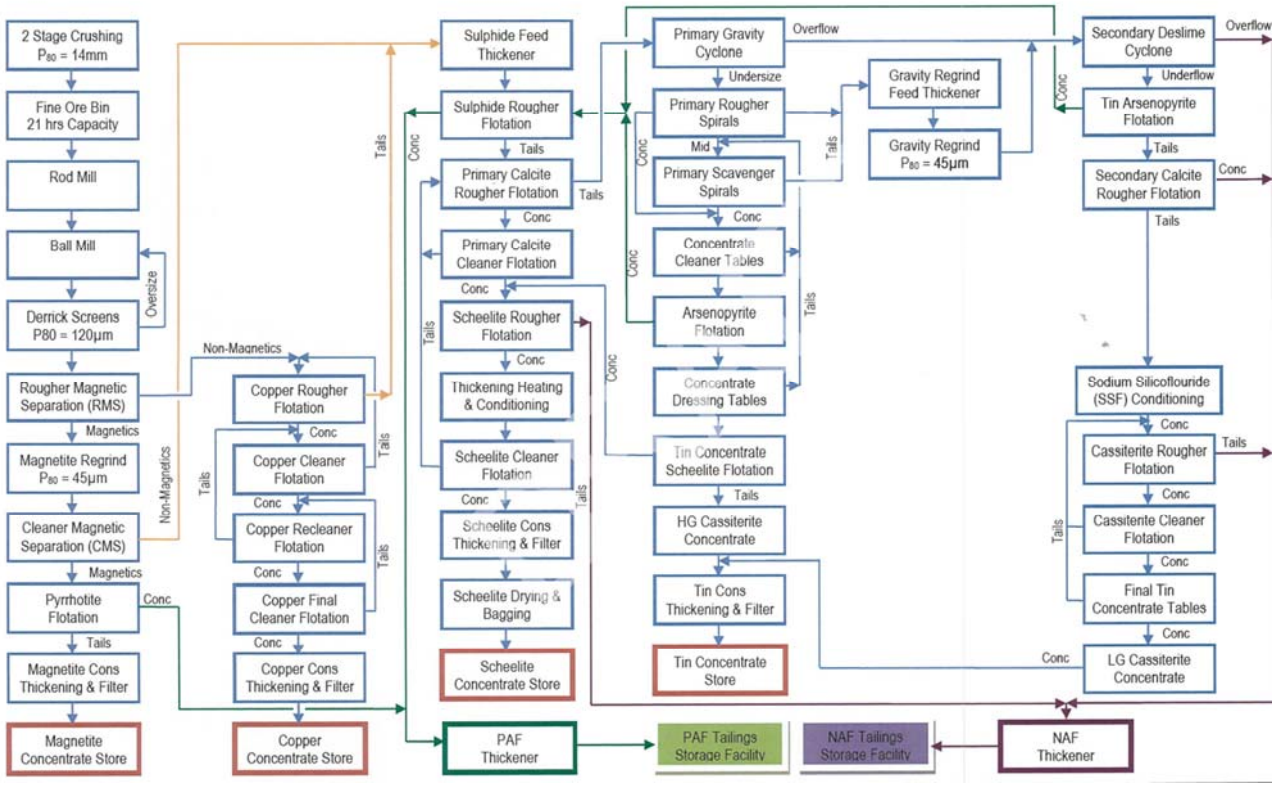

Figure 15: Flow chart of the processing route

7 Data Preparation and Treatment

7.1 Data Spacing and Mineralisation Wireframes

Environmental considerations and rough terrain means that the drilling has not been conducted on a regular grid over the mineralised zones (see Figures 2-6). Drill holes were fanned off a much smaller number of drill pads and drilling pierce points are locally somewhat clustered Drill hole density in the Main Skarn ranges from approximately 25m by 10m to a maximum of c. 120m, and the No.2 Skarn from approximately 20m by 10m to a maximum of c. 120m. Overall drill hole spacing for both skarns is very approximately 40m by 25m.The drill hole density in the Reward Skarn ranges from approximately 25m by 10m to a maximum of c. 100m. The mineralisation wireframes were extended approximately half section spacing beyond the final mineralised drill section.

The mineralisation for Tin, Tungsten and Magnetite at Mount Lindsay is not completely coincident, consequently a different set of wireframes has been created for each commodity by digitising strings onto the irregularly spaced drill sections. For the tin resource a lower threshold of 0.1% Sn was used, for tungsten 0.05%WO_3. For the Magnetite resource a lower cut off of 15% MR (Magnetic Recovery) was chosen. Very minor narrow (<2-4m) and isolated patches of magnetite, Sn and WO_3 mineralisation have been left out of the mineralisation wireframes. Copper grade was not used to define the mineralisation wireframes. The mineralisation wireframes cover approx. 1,300 m strike extent of the Main Skarn, 1,500 m strike extent of the No.2 Skarn, and 600 m strike extent of the Reward skarn. The Main and No.2 mineralisation wireframes are near vertical and split into upper and lower sections by Tulloch Fault.

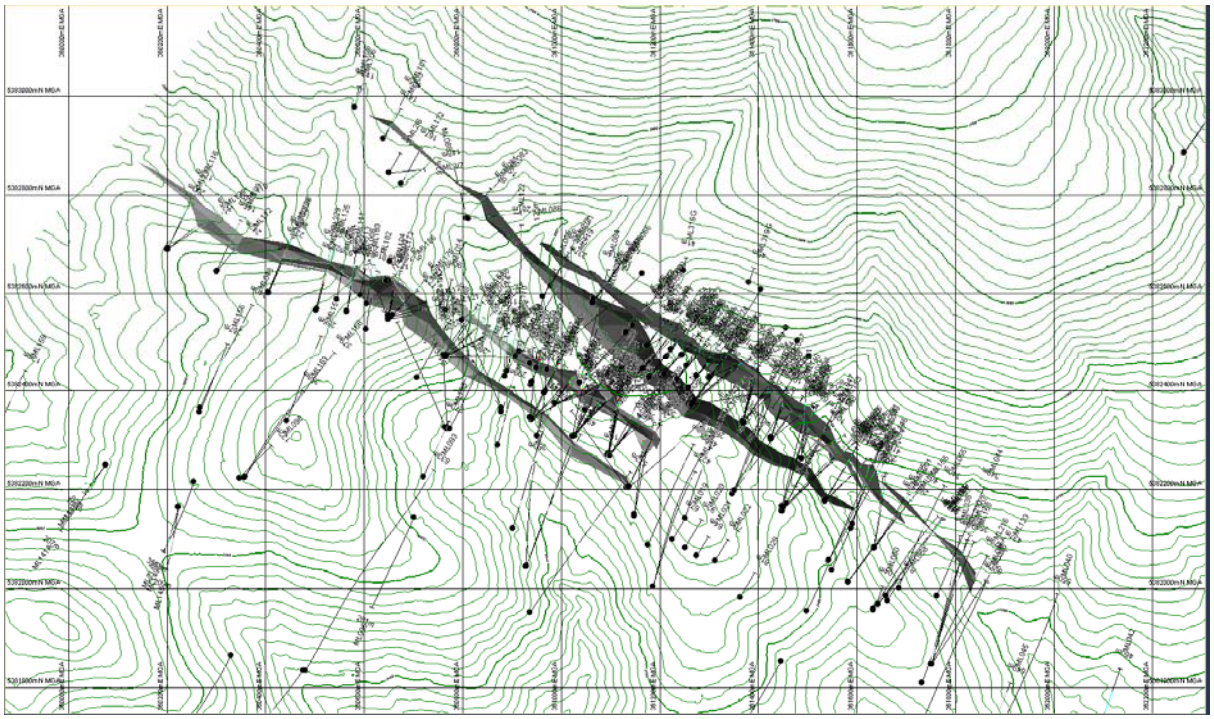

Figure 16: Plan view of Main and No.2 skarns showing drill holes traces (as vertical projections) and the mineralisation wireframes used for the Magnetic Recovery resource estimation (Main Skarn light grey, No.2 Skarn dark grey). The split in each zone is caused by Tulloch Fault, a southeast dipping reverse fault with c. 55-60 m offset. MGA Zone 55 GDA94, 10 m topographic contours.

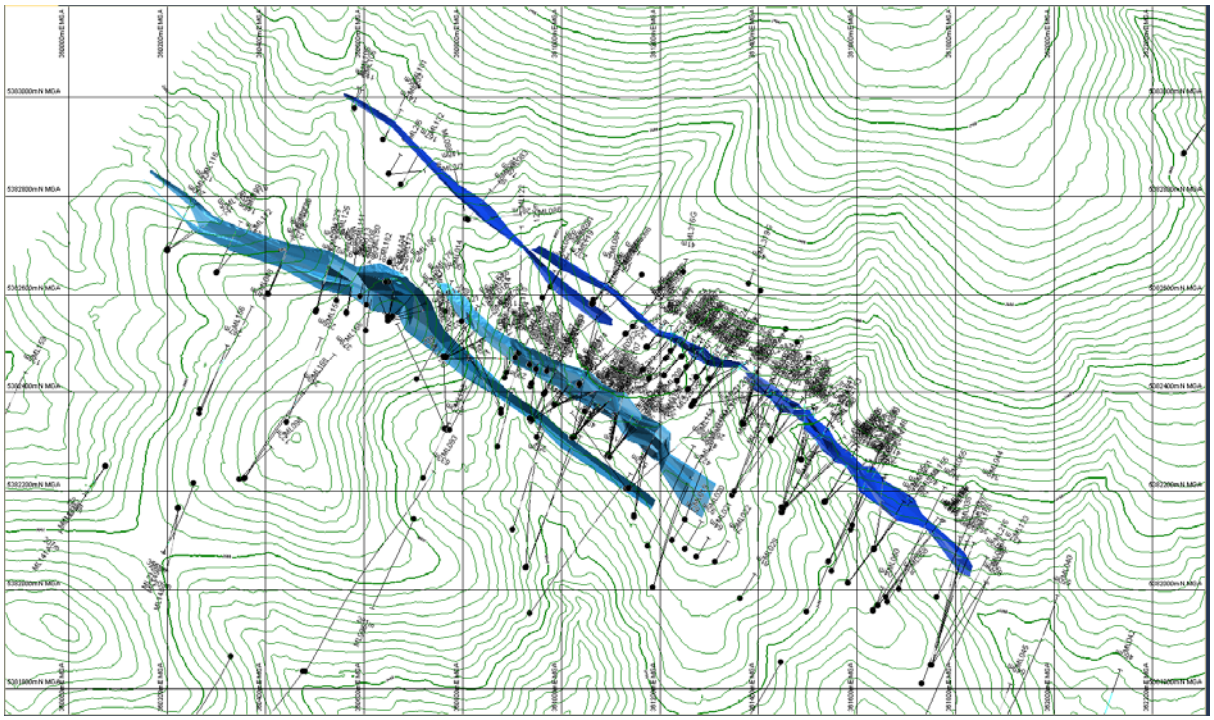

Figure 17: Plan view of Main and No.2 skarns showing drill holes traces (as vertical projections) and the mineralisation wireframes used for the Tin resource estimation (Main Skarn light blue, No.2 Skarn dark blue). The split in each zone is caused by Tulloch Fault, a southeast dipping reverse fault with c. 55-60 m offset. MGA Zone 55 GDA94, 10 m topographic contours.

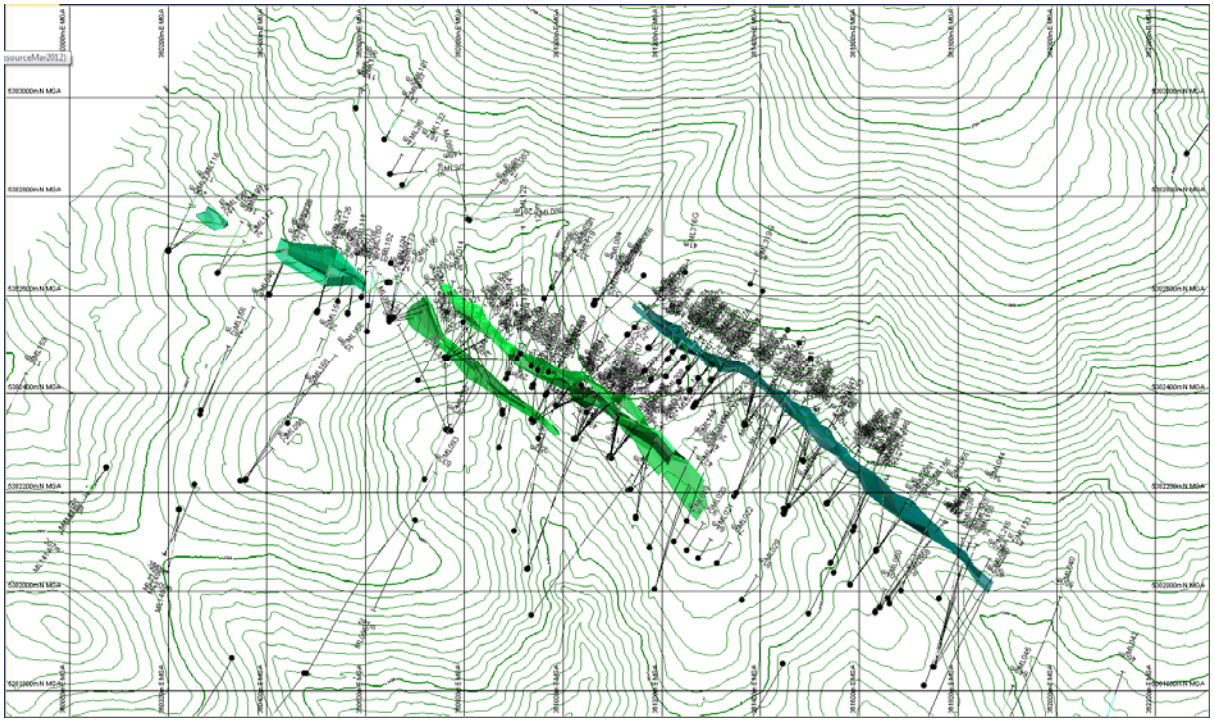

Figure 18: Plan view of Main and No.2 skarns showing drill holes traces (as vertical projections) and the mineralisation wireframes used for the Tungsten resource estimation (Main Skarn light green, No.2 Skarn dark green). The split in each zone is caused by Tulloch Fault, a southeast dipping reverse fault with c. 55-60 m offset. MGA Zone 55 GDA94, 10 m topographic contours.

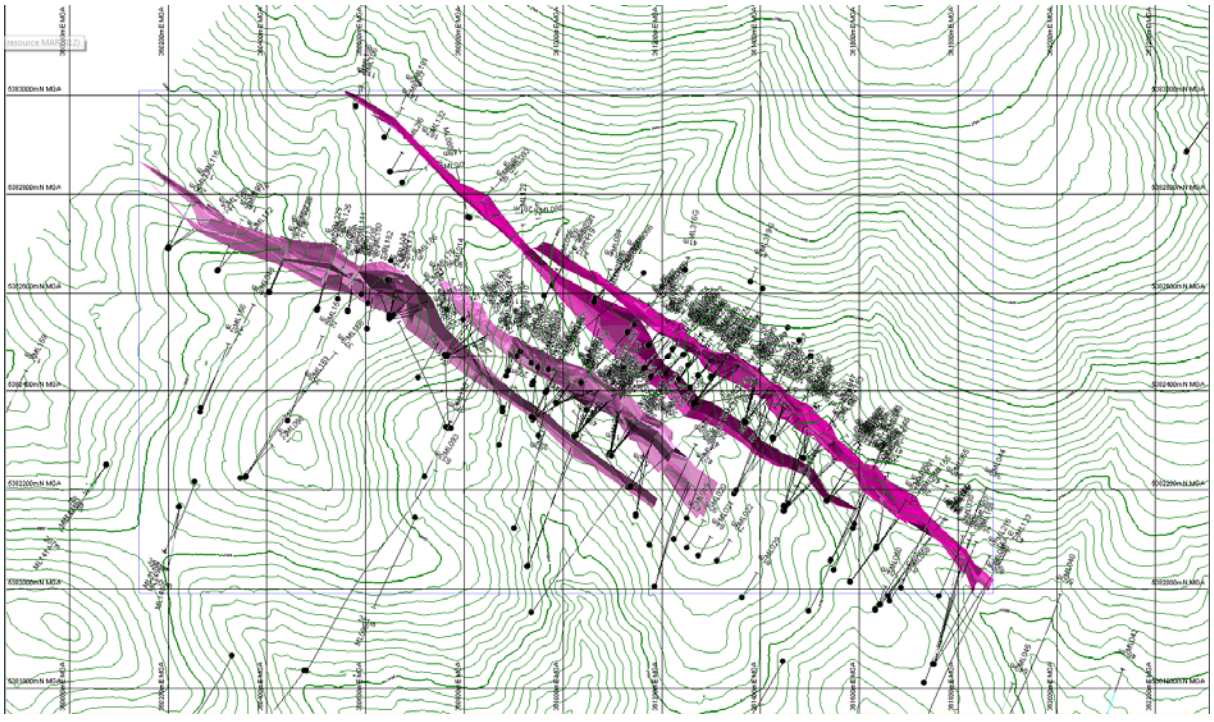

Figure 19: Plan view of Main and No.2 skarns showing drill holes traces (as vertical projections) and the mineralisation wireframes used for the combined resource estimation (Main Skarn light pink, No.2 Skarn dark pink). The split in each zone is caused by Tulloch Fault, a southeast dipping reverse fault with c. 55-60 m offset. MGA Zone 55 GDA94, 10 m topographic contours.

A range of shallow dipping to near vertical mineralisation wireframes were created for the Reward deposit. As the mineralisation of the different commodities is a lot more consistent here, a combined wireframe was created for both tin and tungsten with a lower threshold of 0.1% Sn and 0.05% WO_3. (s. Figure 4)

7.2 Sample Lengths and Compositing

The current estimate was modelled from generally 2m downhole composites, consistent with the dominant sample interval. The weighted average compositing function in Micromine was used for compositing. A different set of composites was created for each commodity, honouring the wireframes enclosing the mineralisation. The mineralisation wireframes were created from raw down hole data and consequently some composites of irregular length were created at the edges of the interpretation. Irregular composites do not account for a significant proportion of the final data sets (Table 3) and will not significantly affect the resource estimate. Each composite was flagged according to wireframed mineralisation domain.

Figure 20: Summary statistics and log histogram for sample lengths, Main Skarn.

Sn&WO3	TOTAL	167	0.1	2	1.79	298.8	100%	100%

Of the total 273 drill holes used for the current Resource estimation some 21 holes for 4,761 m core of mainly BQ size (36.5mm diameter) were drilled by the previous owners Aberfoyle Tin Development Partnership and Renison Limited; the other 250 drill holes for 49,767 m were drilled by Venture Minerals Limited with most of the core used in the resource estimate being HQ size (63.5mm diameter, 51% of samples) and NQ size (47.6mm diameter, 40% of samples). The rest of samples were taken from BQ size core (36.5mm diameter, 7% of samples), PQ size core (85mm diameter, 1% of samples) and less than 1% combined of samples taken from other drill methods (AX size core, percussion drilling and adit channel sampling).

Venture's drill core was mostly sampled in 2 m intervals and accounts for 96 % of the assays. Drilling by Renison was generally sampled in 1 m lengths and accounts for 4% of the assays. Only composite or summary assays representing intervals ranging from 1.8 m to 36.2 m length were available for the Aberfoyle drill holes and represents <1% of the assay dataset.

7.3 Density

Density was mostly collected on a 1 m basis from the Venture drill core, composited and merged with the 2 m assay composite file. The Main Skarn contains a significantly greater proportion of sulphide compared with the No.2 Skarn (magnetite dominant) and consequently has a lower mean density. The mean composited density for fresh Main Skarn is 3.52 t/m^3, for the No.2 Skarn mean density of the fresh composites is 3.64 t/m^3, and Reward Skarn 2.1 t/m^3 (Figure 22 to Figure 24).

Very minor parts of the Main and No.2 skarns, most of the Livingstone Skarn and all of the Reward Skarn as currently defined by drilling are weathered to clay and gossan. Densities for weathered materials were determined by volumetric techniques on core and geophysical logging (downhole density by gamma radiation). A density of 1.7 t/m^3 has been selected for clay and 2.6 t/m^3 for gossan.

Table 5: Densities for weathered materials

Lithology	Density by weight and volumetric methods on recovered core	Density by downhole gamma tool	Preferred density
clay	1.59-1.86 t/m^3	1.93-2.11 t/m^3	1.7 t/m^3
gossan	2.12-2.98 t/m^3	2.43-2.66 t/m^3	2.6 t/m^3

The clay zones were wireframed from drill hole logging data and used to assign appropriate weathering codes to the block model. Blocks coded "clay" were assigned a density of 1.7 t/m3.

For Main and No.2 skarns ensities in blocks outside the clay zones were interpolated into the single commodity wireframes, using the IDS (Inverse Distance Squared) technique, using the same search ellipses as for the metals. Four Sectors were used for each search ellipse, with a maximum of 6 samples per sector. The Reward deposit consists mainly from clay, so the densities were estimated using the same estimation method as for the metals without assigning a generic density.

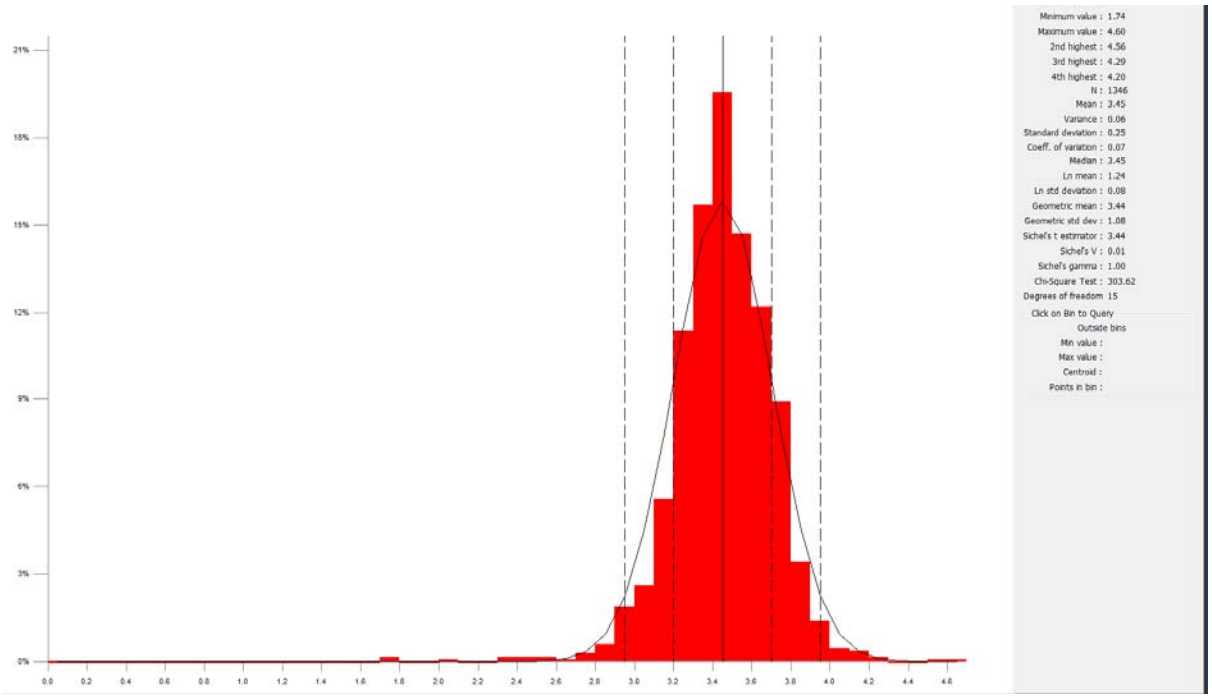

Figure 22: Main skarn composited fresh densities

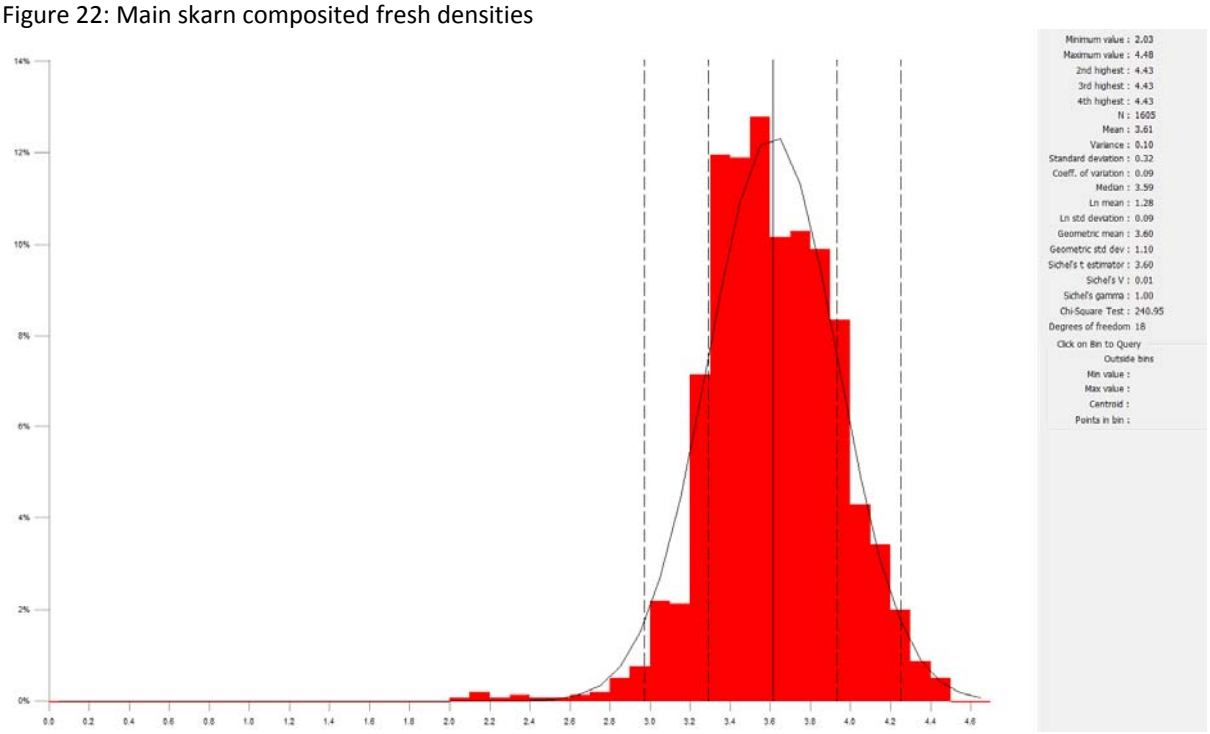

Figure 23: N2 Skarn composited fresh densities

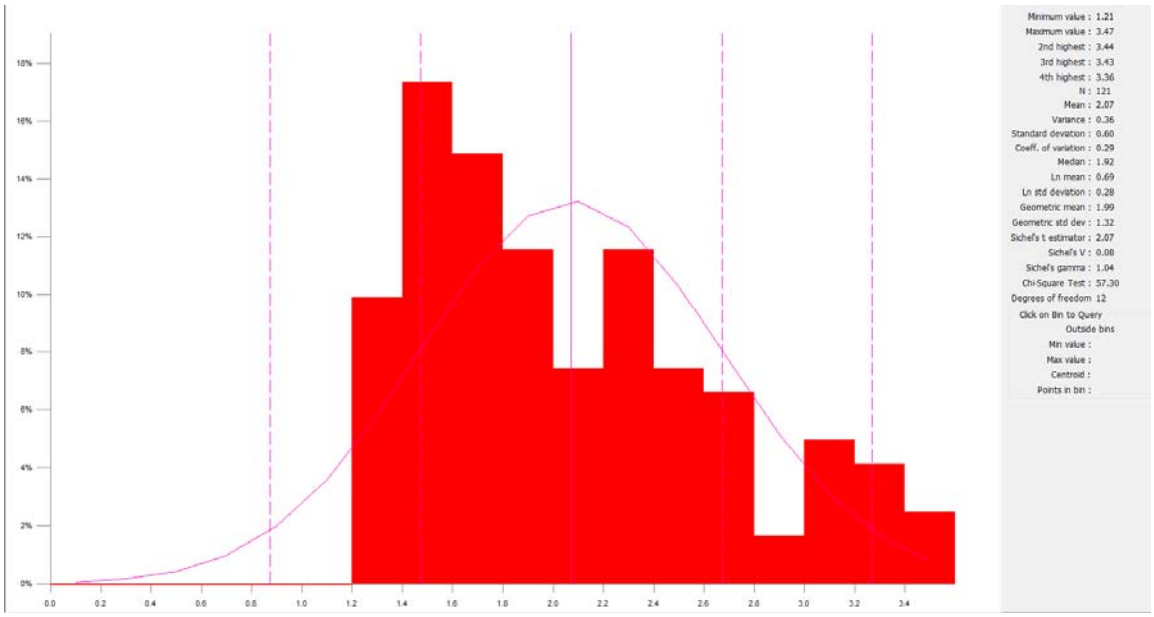

Figure 24: Reward skarn composited densities

7.4 Magnetic Recovery

The Mass Recovery (MR) of the iron was determined by DTR analyses for 90% of the composited assay intervals used for the estimation. Gaps in the DTR data were filled with MRs derived from the magnetic susceptibility data via the equation MR = 0.0456 x magnetic susceptibility in 10-3 SI units Magnetic susceptability is positively correlated with the MR by DTR (Figure 22) and was collected for all Venture drill core and 94 % of the Renison drill core.

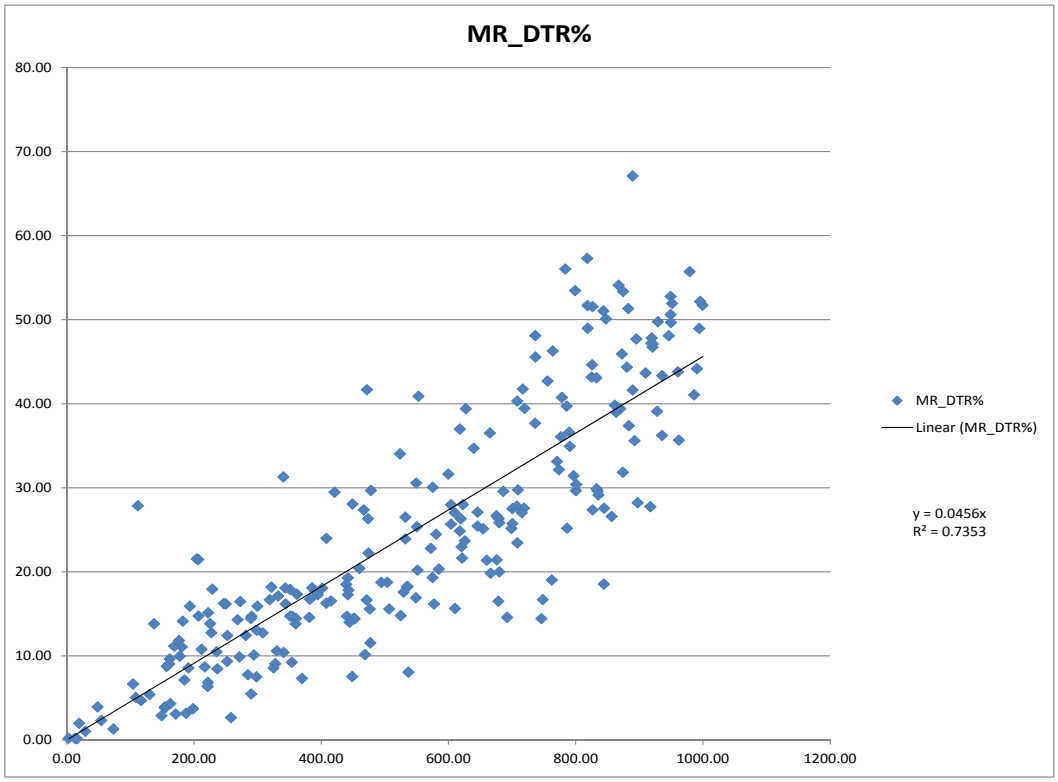

Figure 25: Regression of Magnetic susceptibility 10^{-3} SI units (x-axis) vs. DTR (y-axis)

8 Resource Modeling

8.1 Modeling Domains and Block Model Extents

As mentioned in Section 7.1 three-dimensional wireframes were created using Micromine by digitising strings onto drill sections spaced between c. 25 and 100 m apart to encompass the combined magnetite, Sn and WO_3 mineralisation and constrain the resource estimation. Thresholds for wireframing were approx. 20 % magnetic recovery, 0.1 % Sn or 0.1 % WO_3.

In the Main and Number 2 skarns, four discrete wireframes were created for the magnetite and tin resources, three for the tungsten resource. The separation is a result of offset of all mineralised zones across Tulloch Fault. There is no tungsten above cutoff grade below Tulloch Fault in the Number 2 skarn. All wireframes were clipped to the LiDAR DTM and the DTM of Tulloch Fault. Each wireframe beneath Tulloch Fault, apart from the Number 2 Skarn Magnetite, was then also split into two geometric subdomains, as well as the wireframe for tungsten above Tulloch Fault in the Number 2 Skarn. This resulted in a total of 16 domains (6 for Tin, 5 each for tungsten and magnetite) as listed in Table 6.

Table 6: Wireframe domains and volumes. Abbreviations M = Main Skarn, N2 = Number 2 Skarn, AT = Above Tulloch Fault, BTE = Beneath Tulloch Fault Eastern domain, BTW = Beneath Tulloch Fault Western domain.

WF_NAME	**VOLUME**
SN_M_AT	1,566,323

MT_M_AT	339,009
MT_M_BTE	727,978
MT_M_BTW	537,544
MT_N2_AT	2,661,506
MT_N2_BT	1,791,315
MR TOTAL	**6,057,352**
combined resource	

Three separate models, MR (Magnetic Recovery), Sn and WO3 were created with blocks of 10m x 5m x 2.5m using the parameters in Table 2 and trimmed to the corresponding wireframes using 2.5 x 2.5 x 1.25m sub blocking.

Table 7: Blockmodel extents Main and No.2 Skarns

	Origin block centre	block dimensions	Number of Blocks
East	360100	10	191
North	5381900	5	321
RL2000	1800	2.5	361

For the Reward Skarn, only one set of wireframes with four domains was created. The tin and tungsten mineralisation is much more coincident in this deposit, magnetite mineralisation is negligible. Patchy haematite mineralisation exists, but was ignored for this resource estimation. All wireframes were clipped to the LiDAR DTM. Reward wireframing domains and volumes are listed below.

Table 8: Wireframe domains and volumes for Reward (RW) skarn. Abbreviations N = Northern Lode, H = Hanging Wall Lode, C = Central Lode, F = Footwall Lode

WF name	**Volume**
RW_N	19,651
RW_H	29,700
RW_C	82,473
RW_F	143,485
TOTAL	**275,309**

One blockmodel was created with blocks of 10m x 5m x 2.5m using the parameters in Table 9 and trimmed to the corresponding wireframes using 2.5 x 2.5 x 1.25m sub blocking.

Table 9: Blockmodel Extents for Reward Skarn

	Origin block centre	block dimensions	Number of Blocks
East	357600	10	61
North	5382200	5	81
RL2000	2050	2.5	85

8.2 Search Geometry and Criteria and Semi Variograms

Wireframing, statistical evaluation and geostatistical modelling and 3D block modelling have been carried out by Venture Minerals using Micromine software.

8.2.1 Main and No.2 Skarn

The MR, Sn and WO3 grades were interpolated to the blocks using the ordinary kriging method. Dips, strikes and ranges of the initial search ellipses were determined from variograms and, from obvious geological features for the domain. Nine progressively more relaxed searches were performed until all blocks were assigned a grade.

Dips, strikes and ranges of the initial search ellipses were determined from variography supported grade*thickness long sections and geology. Variograms and search criteria for each resource and domain are listed below. All variography is based on the domains above Tulloch fault (highest data density), the

same ranges, sills and nuggets were applied to the other domains. Boundaries between domains were hard.

8.2.1.1 Magnetic Recovery (MR) Variography

a) Main Skarn Variography

Directional semi variograms show ranges of c. 70 m for MR within the Main Skarn. The histogram indicates a single grade population. Semi variogram model parameters used for the OK estimation on the Main Skarn are listed in Table 10 and Table 11.

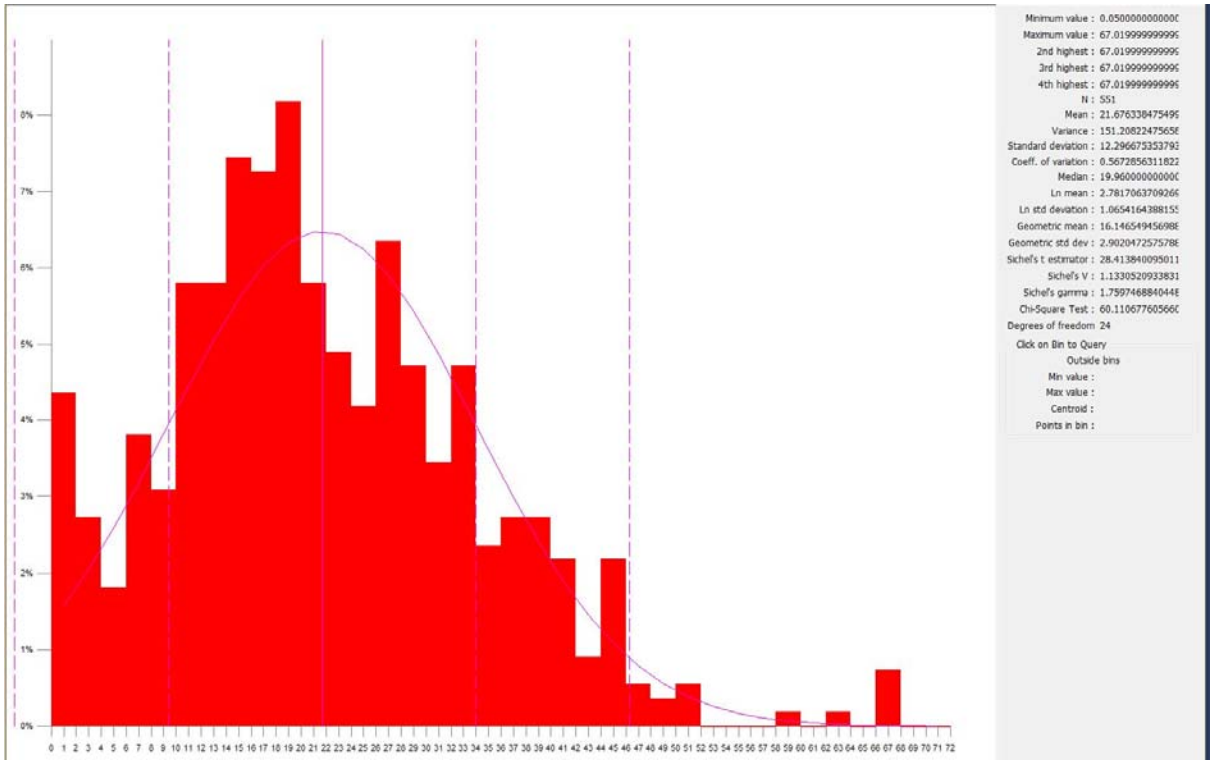

Figure 26: Summary statistics and normal histogram for composite MR grades, Main Skarn.

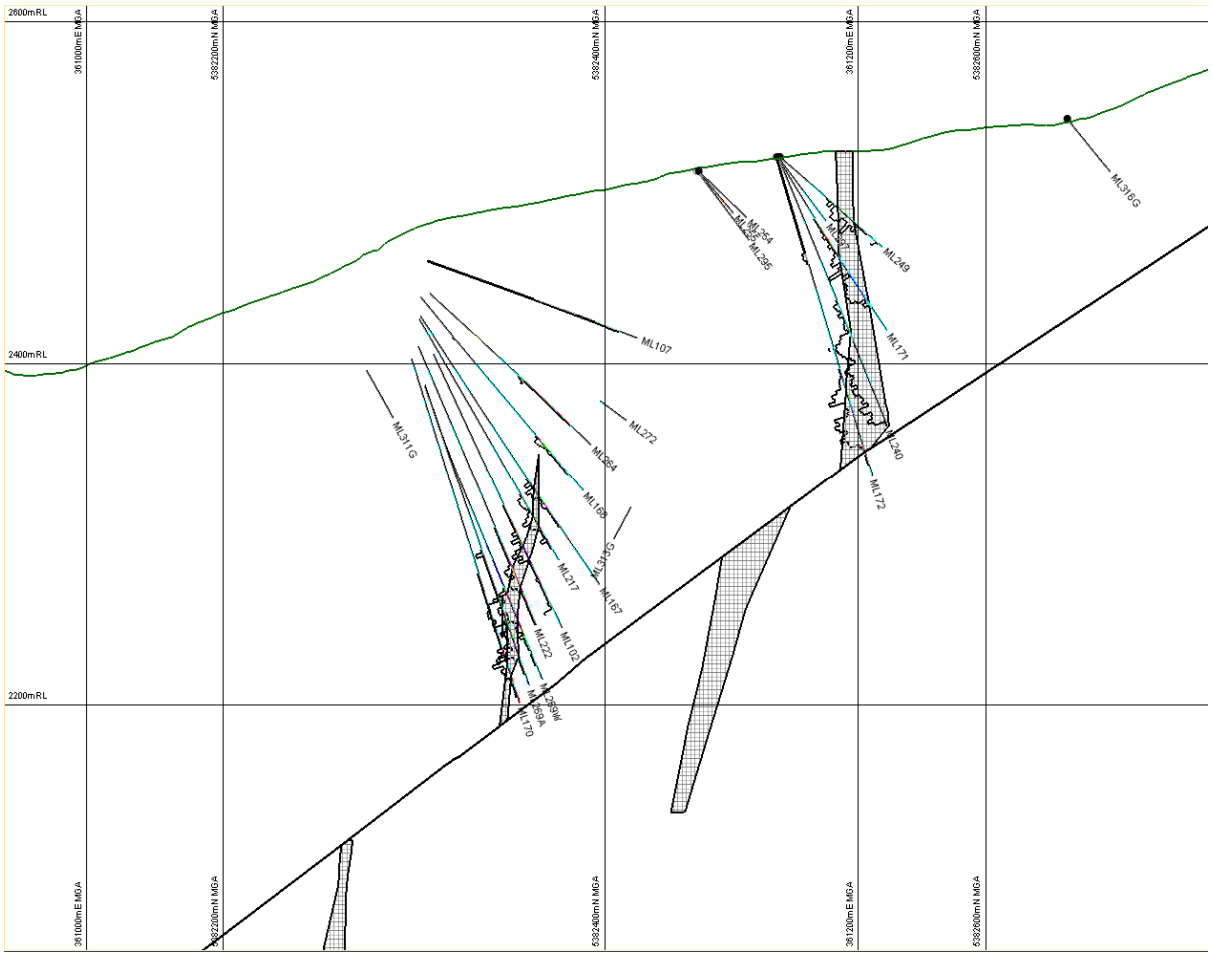

Figure 27: Cross section looking towards MGA NW of the Main Skarn (left) and No.2 Skarn (right) MR mineralisation wireframes with drill hole traces colored by lithology (pink = granite, grey = sandstone & siltstone, red = fault zone, blue = pyroxene skarn, green = amphibole and magnetite skarn, black = magnetite skarn, magenta = sulphide & biotite skarn, orange = clay). black graph on left of drill traces MR%. Separation of the No.2 Skarn (and Main Skarn off bottom of view) into upper and lower parts is the result of offset on Tulloch Fault. X and Y coordinates MGA Zone 55 GDA94, RL AHD83 + 2000 m

b) Number 2 Skarn Variography

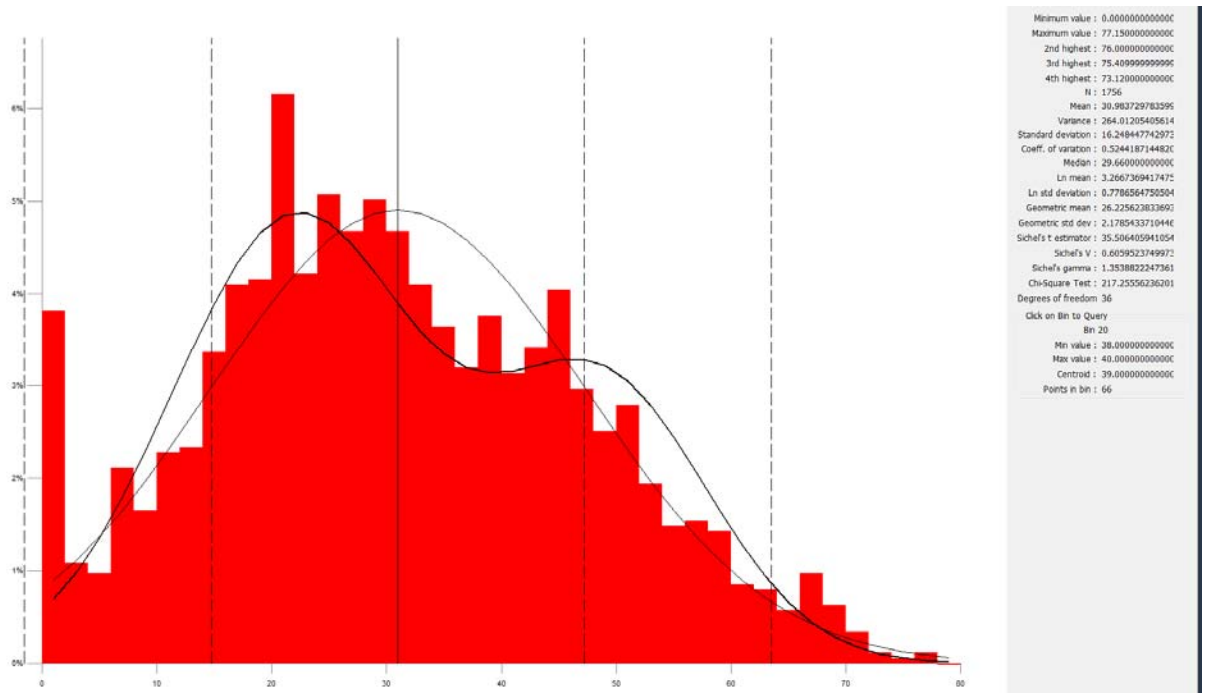

Figure 31: : Summary statistics and normal histogram for composite MR grades, N2 Skarn.

The MR histogram for all composites inside the resource wireframe for the Number 2 Skarn indicates a bimodal distribution, with a low grade and a high grade population.
Samples were coded to distinguish between high grade (MR>33, code 1) and low grade (MR<33, code 0)
A probablility blockmodel (ID2) was created using those codes, to reveal a possible high grade zone inside the magnetite wireframe.

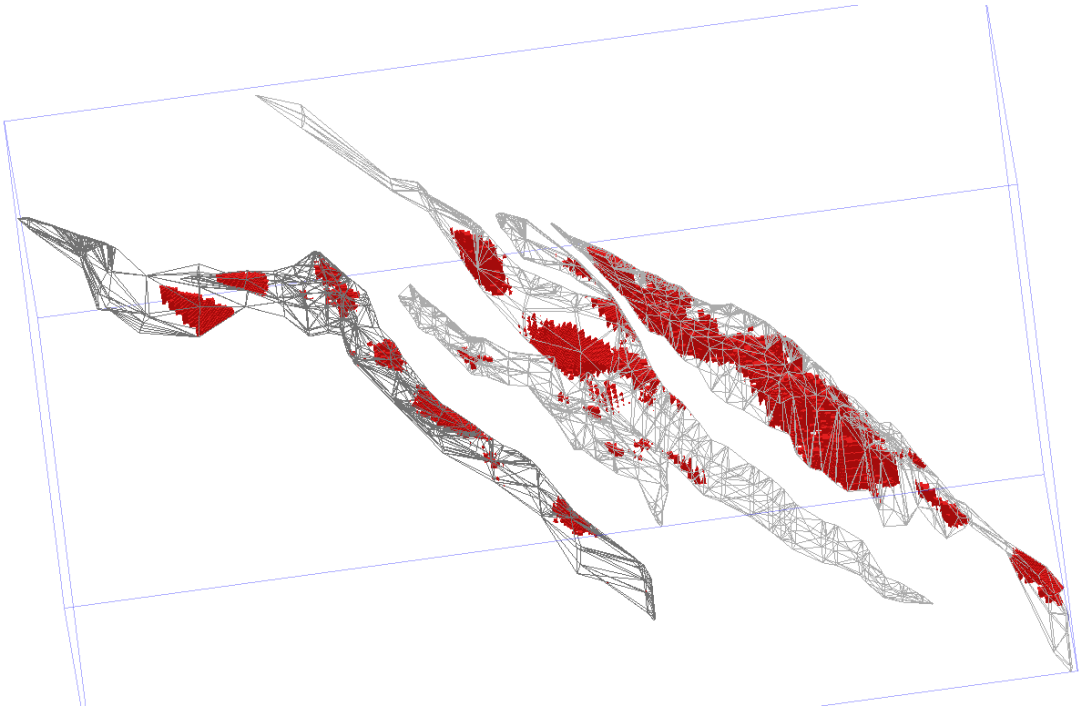

Figure 32: Probable high grade zone (red) inside magnetite wireframe (probability > 0.5), Main and N2 skarns.

A grade shell wireframe was created around the >0.5 probability blocks and the samples inside the new wireframe coded as high grade. New histograms for samples inside and outside the high grade zone show single populations.

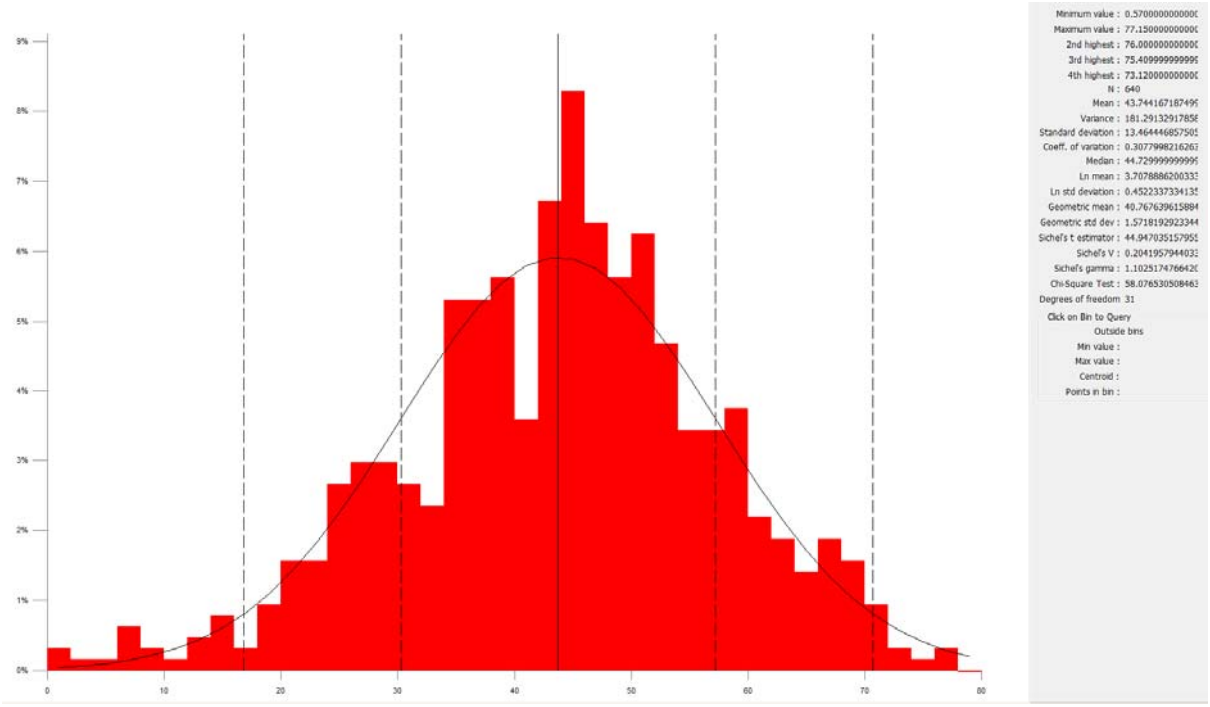

Figure 33: MR Histogram for composites inside high grade shell

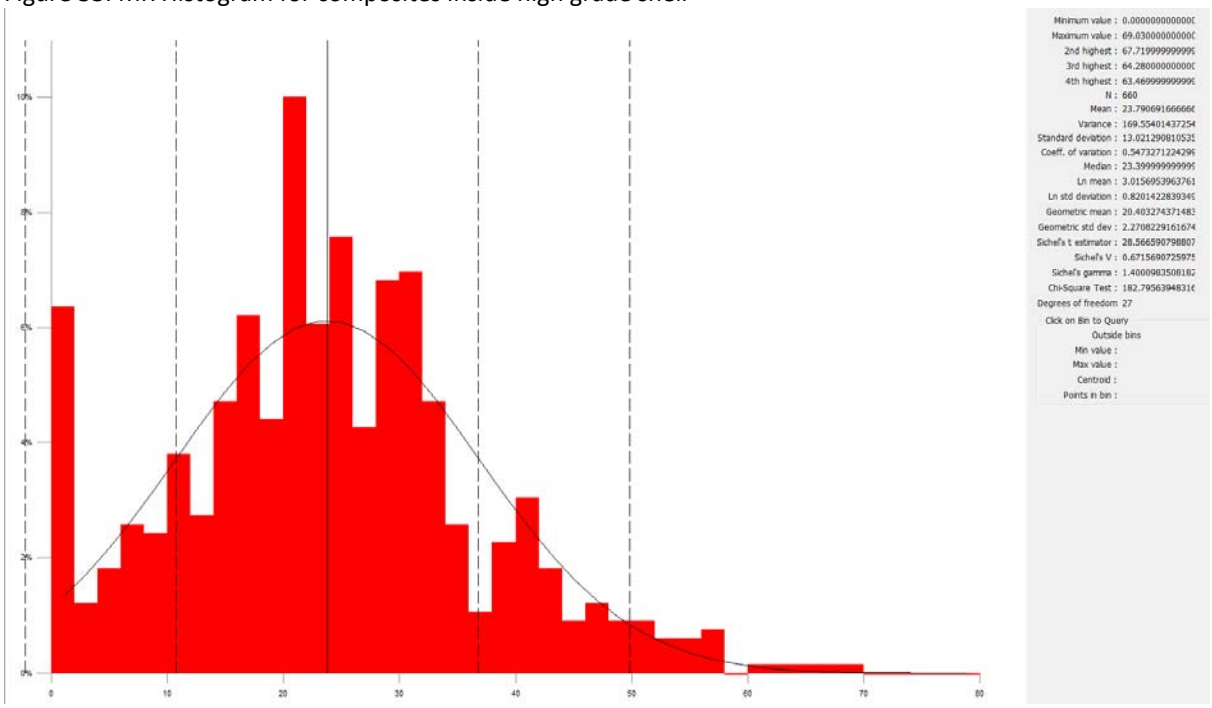

Figure 34: MR Histogram for composites outside high grade shell

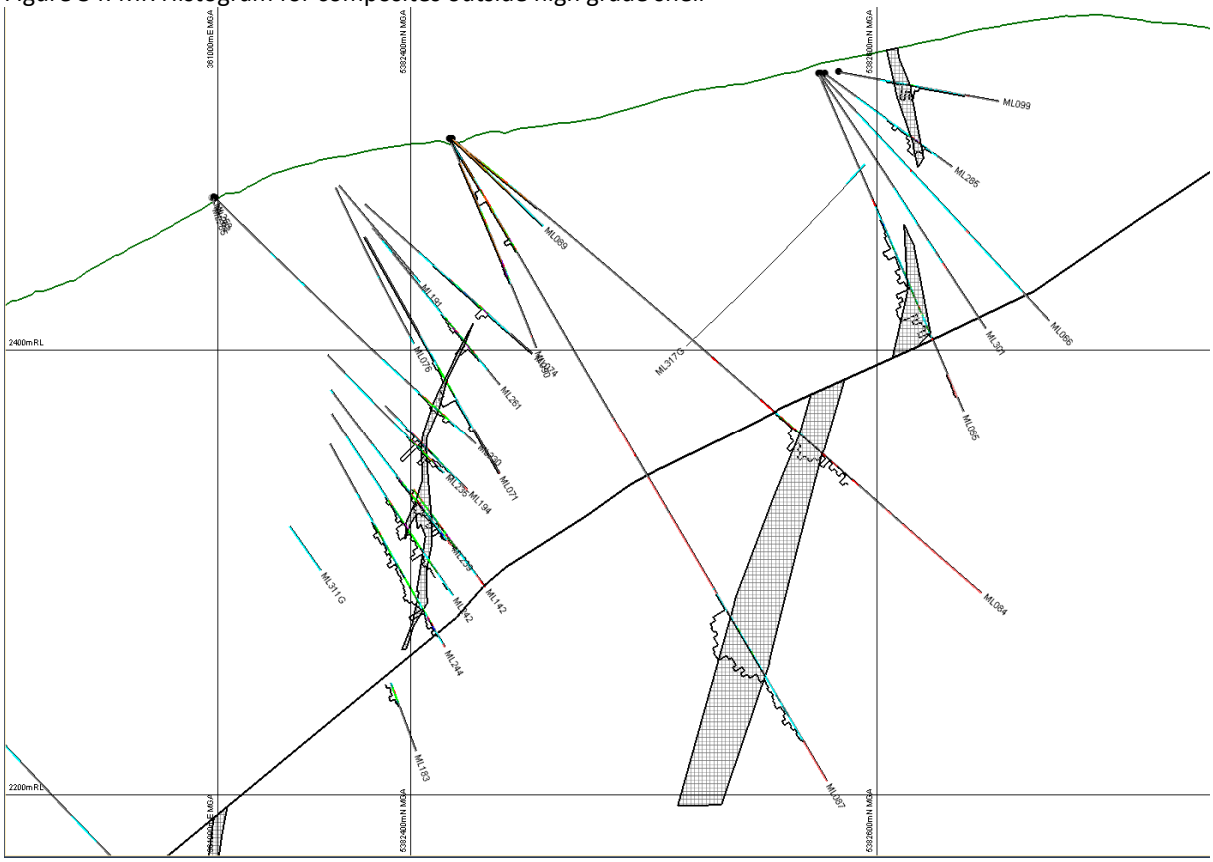

Figure 35: Cross section looking towards MGA NW of the Main Skarn (left) and No.2 Skarn (right) MR mineralisation wireframes with drill hole traces colored by lithology (pink = granite, grey = sandstone & siltstone, red = fault zone, blue = pyroxene skarn, green = amphibole and magnetite skarn, black = magnetite skarn, magenta = sulphide & biotite skarn, orange = clay). black graph on left of drill traces MR%. Separation of the No.2 Skarn (and Main Skarn off bottom of view) into upper and lower parts is the result of offset on Tulloch Fault. X and Y coordinates MGA Zone 55 GDA94, RL AHD83 + 2000 m

Directional semi variograms show ranges of c. 767m for MR within the high grade zones of the No. 2 Skarn, c. 40m for the low grade zones. Semi variogram model parameters used for the OK estimation on the Main Skarn are listed in Table 12 and Table 13

8.2.1.2 Sn variography

a) Main Skarn Variography

The histogram for Sn shows a single population of grades with some high grade outliers. As the data is highly positively skewed on a normal scale, all variography was performed on a logarithmic scale.
A topcut of 10% was applied to the Sn values to avoid over-estimation by extreme outliers.
Directional Variograms for Main Skarn show a range of around 70m in the predominant strike and dip directions of the orebody. Above Tulloch fault, the wireframe was split into an eastern and a western domain, to adjust the search ellipse for the slightly differing plunge of the orebodyb (s.Figure 44: Main skarn Sn assays with Sn-contours and areas of continuity .
Semi variogram model parameters used for the OK estimation of Sn on the Main Skarn are listed in Table 14 and Table 15)

A 50-60 m range is shown for WO3 and >330 m for MR within the No.2 Skarn, while Sn is more complicated with suggestion of a short range (c. 25m) at higher grades and a very long range (c. 300 m) at low grade (0.1 % Sn). Similar ranges were obtained from directional semi variograms and are within the average drill spacing for a large part of the Main and No.2 skarns (i.e. drill hole spacing in the Main Skarn ranges from approximately 15 m by 30 m to a maximum of c. 150 m, and for the No.2 Skarn from approximately 30 m by 30 m to a maximum of c. 200 m).

8.2.1.3 WO3 Variography

a) Main Skarn Variography

The histogram for WO_3 shows a single population of grades. As the data is highly positively skewed on a normal scale, all variography was performed on a logarithmic scale.
Directional Variograms for Main Skarn show a range of around 70m in the predominant strike and dip directions of the orebody. Above Tulloch fault, the wireframe was split into an eastern and a western domain, to adjust the search ellipse for the slightly differing plunge of the orebody (s.Figure 55).
Semi variogram model parameters used for the OK estimation of Sn on the Main Skarn are listed in Table 18 and Table 19)

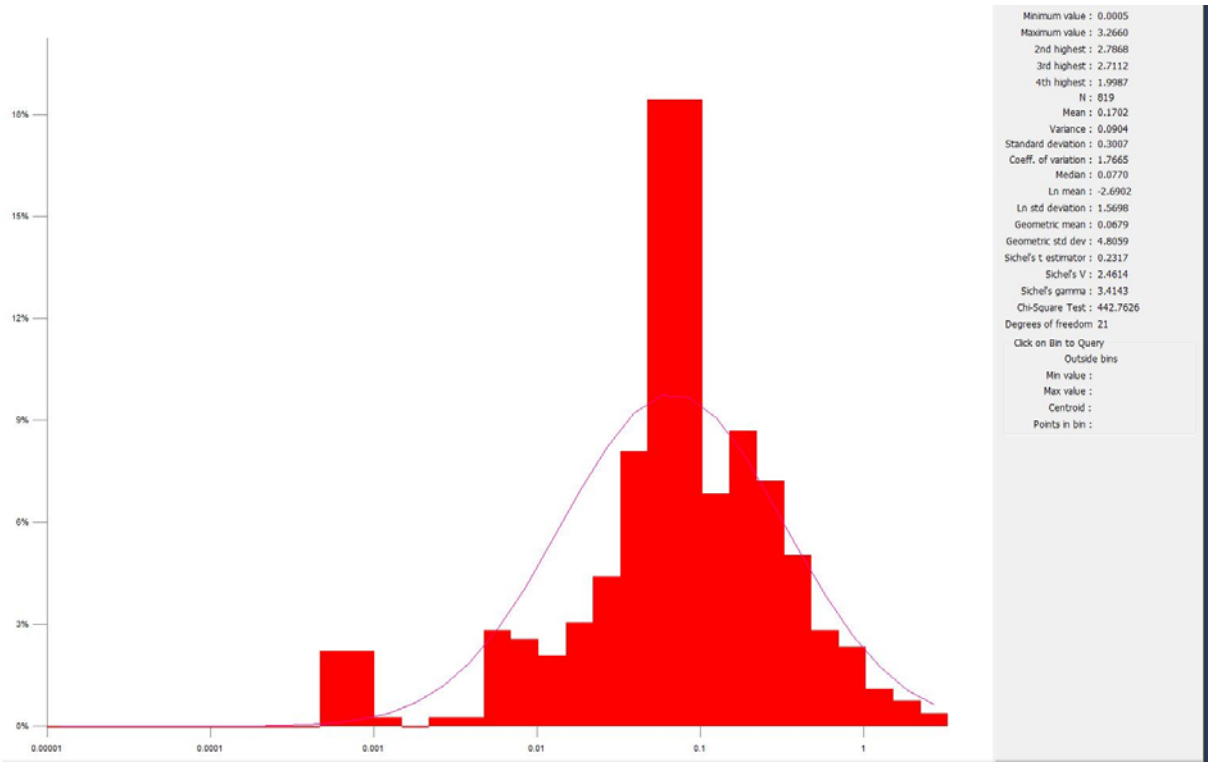

Figure 54: Summary statistics and log histogram for composite WO3 grades, Main Skarn.

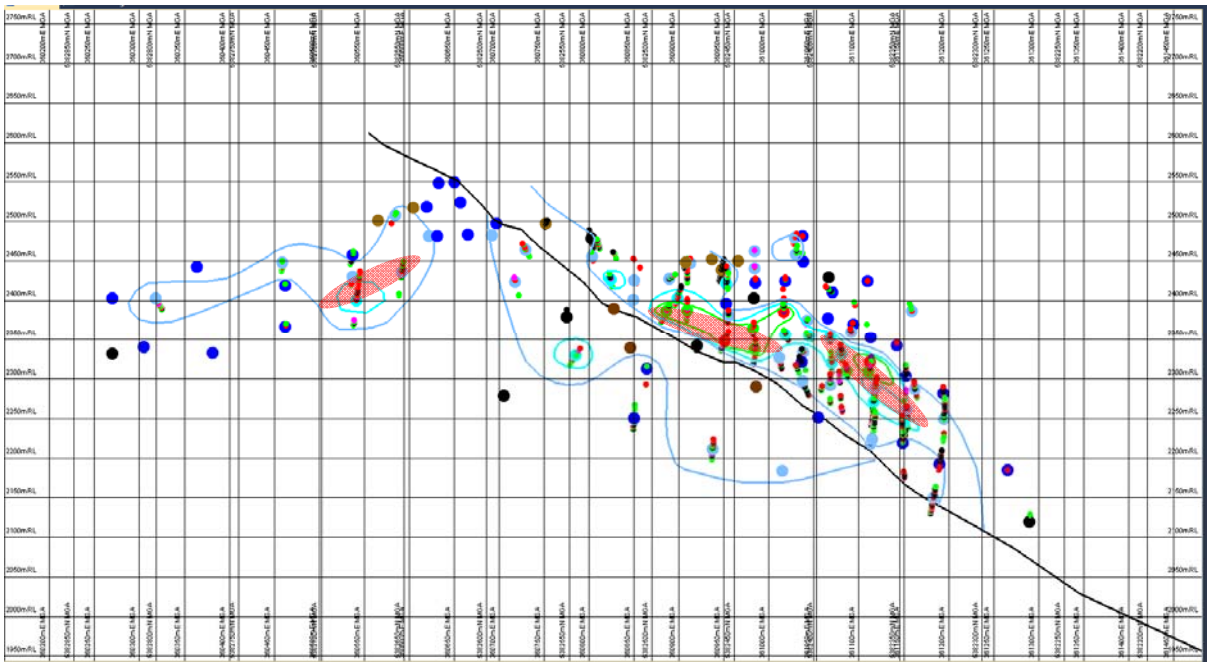

Figure 55: Main Skarn long section with WO3 contours, assays and areas of continuity

Similar to the Magnetite, below Tulloch fault the dip direction of the deposit and mineralisation changes around 360650E MGA with the geometry of the underlying granite. For this reason, the wireframe was again split into an eastern and a western domain.

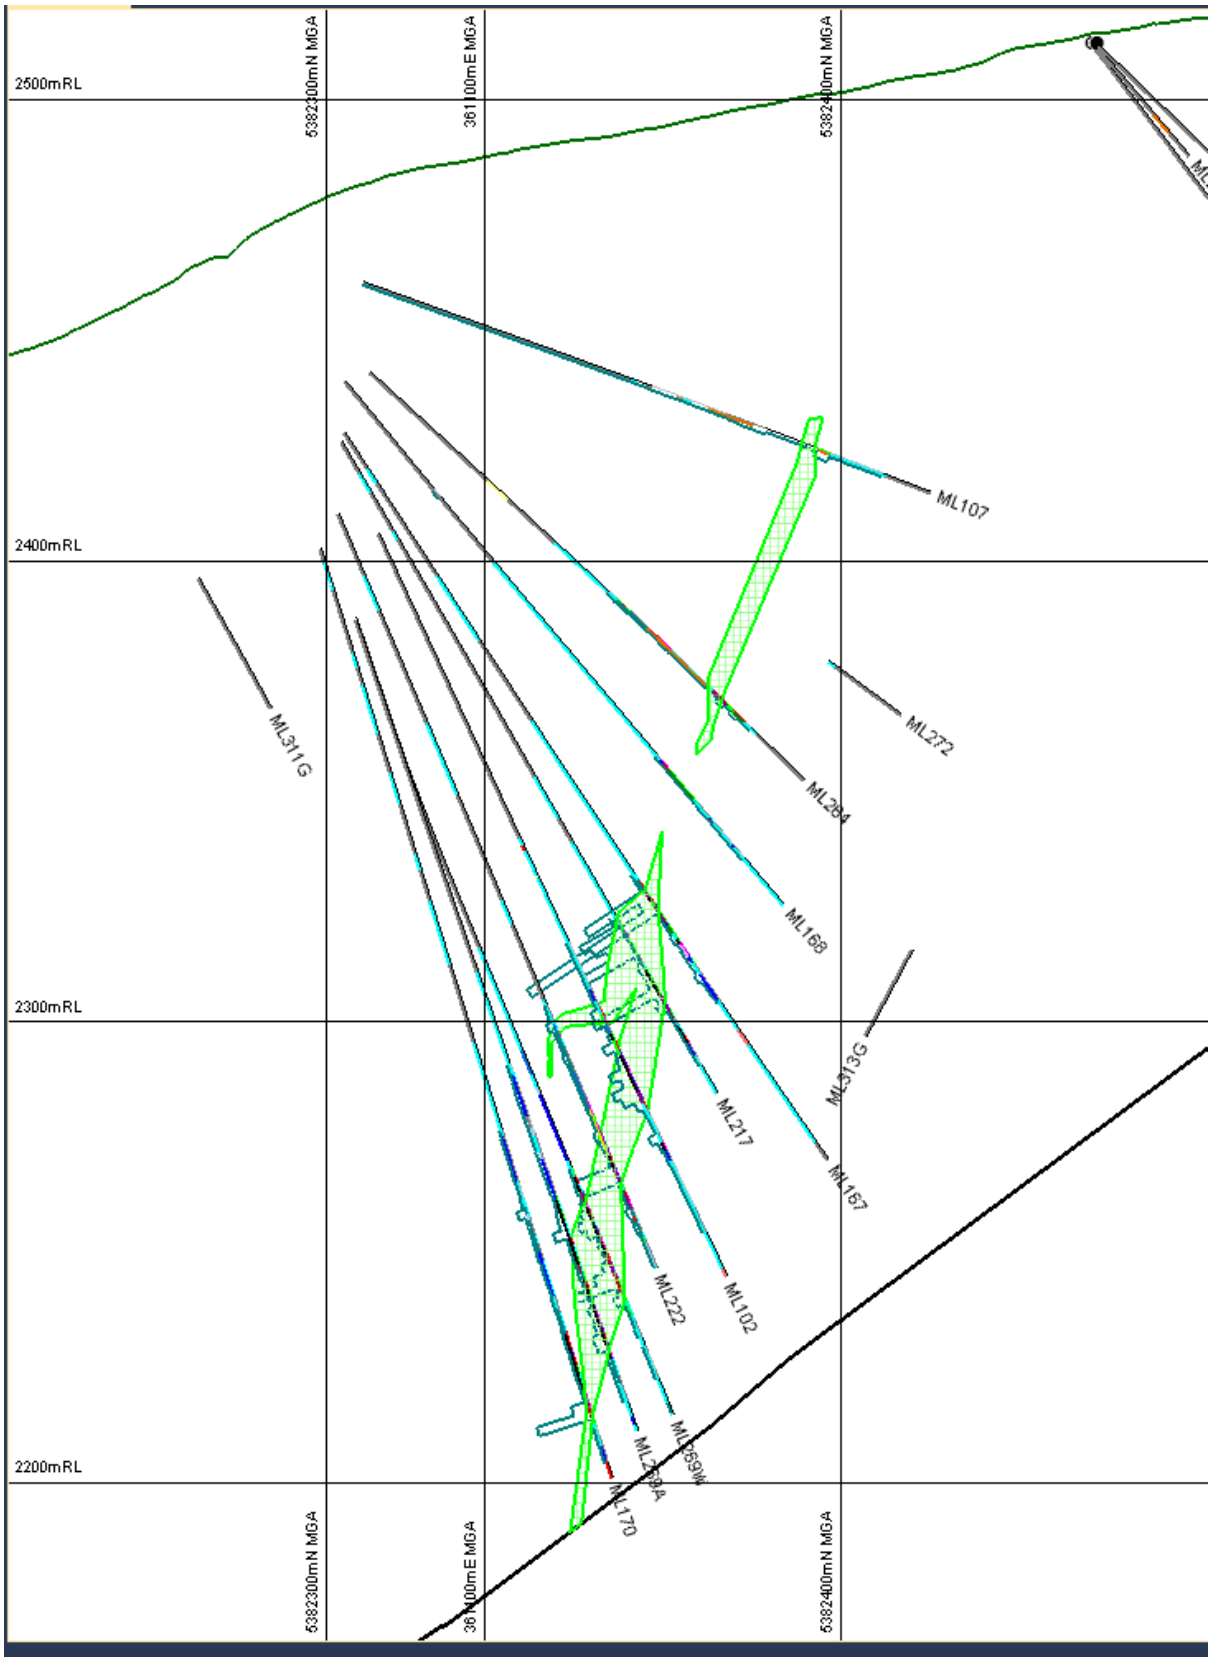

Figure 56: Cross section looking towards MGA NW of the Main Skarn. b) No. 2 Skarn Variography

The histogram for WO_3 shows a single population of grades with some high grade outliers (Figure 60). As the data is highly positively skewed on a normal scale, all variography was performed on a logarithmic scale.

A topcut of 4% was applied to the WO_3 values to avoid over-estimation by extreme outliers.

Directional Variograms for No.2 Skarn show a range of around 60m in the predominant strike and dip directions of the orebody. Above Tulloch fault, the wireframe was split into an eastern and a western domain, to adjust the search ellipse for the slightly differing plunge of the orebodyb (s.Figure 44: Main skarn Sn assays with Sn-contours and areas of continuity . No.2 skarn shows a significant change in dip from west to east. It was decided to split WO3_N2_AT into two domains at 361550 E MGA.

Variography was performed on the dataset for the western domain with higher data density. As the general shape of the continuity lenses appears to be the same in both domains, the same nuggets, sills and ranges will be applied in different directions.

Semi variogram model parameters used for the OK estimation of Sn on the No.2 Skarn are listed in Table 20 and Table 21)

8.2.2 Combining the blockmodels

After estimating and validating the blockmodels for the single commodities, the three separate models were combined into one model using Micromine's "add 2 blockmodels" function.
The separate wireframes for all commodities were also combined using Micromine's Boolean "Solid Union" function, to create a wireframe enveloping the whole resource.
A new composite file within this wireframe was created, including all the domain coding for the single wireframes. Blocks outside a single resource were assigned a grade for that resource using the IDS function on samples outside the corresponding wireframes.

Table 22: Search criteria for filling gaps in combined resource model.

8.2.3 Copper

No separate wireframe was created for copper due to the generally low grades across the deposit. Copper grades were estimated into the combined wireframe using the IDS technique. Four Sectors were used for each search ellipse, with a maximum of 6 samples per sector. Search criteria are outlined in Table 24. Grade Histograms for both the Main and No.2 Skarns indicate single populations (Figure 66 and Figure 67)

Deposit	Element	Dip	Azimuth	Plunge
MAIN	CU	90	125	30
N2	CU	90	125	30

8.2.4 Reward Skarn Estimation

Due to the curving geometry of the Reward Skarn Resource wireframes and the relatively small number of samples, no meaningful variography could be obtained. The estimation was carried out in the Inverse Distance estimation method to the power of 2.

The search ellipse was oriented parallel to the general strike and dip of the orebody, with an azimuth of 125 degrees, a dip of -85 degrees and Plunge of 15 degrees. Four sectors were used for each search ellipse with

a maximum of 4 points per sector, and a minimum of 3 points for the first search followed by a minimum of 2 points for subsequent searches. The boundaries between domains were hard.

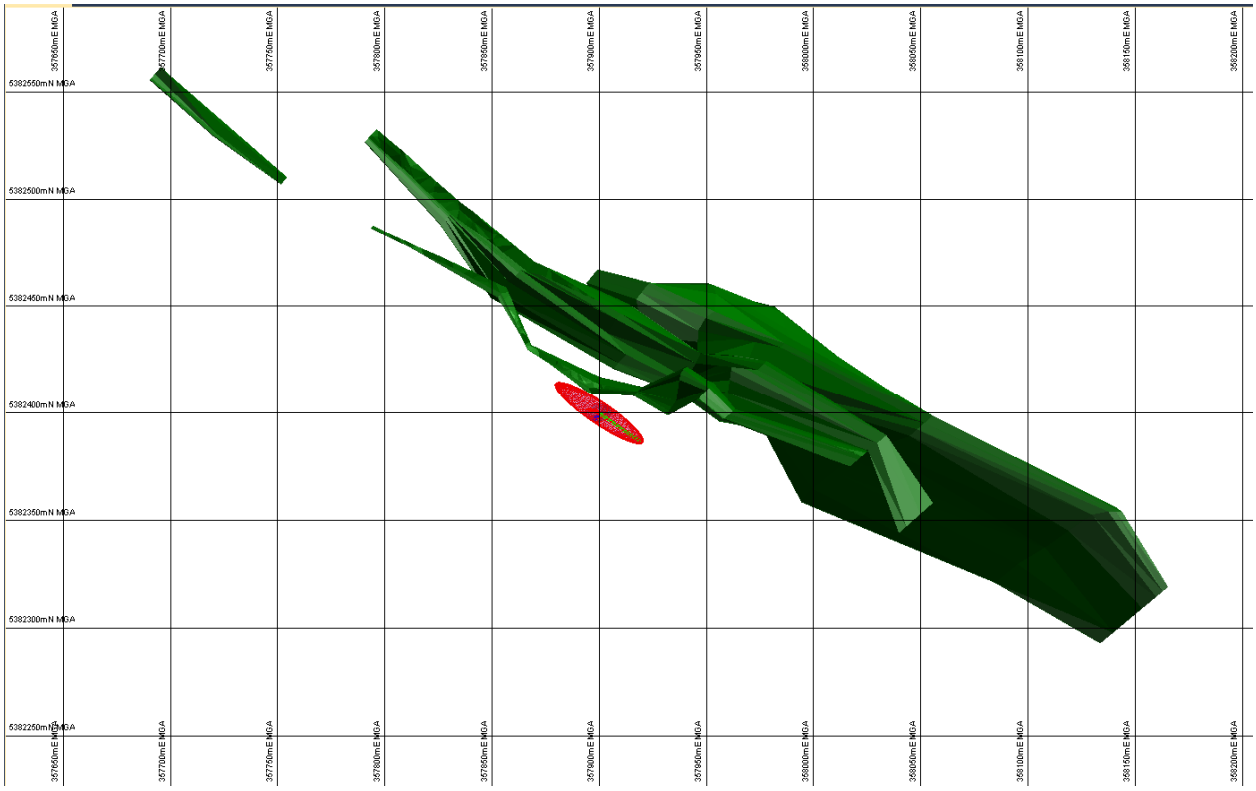

Figure 68: Plan view of Reward mineralisation wireframes (green) with search ellipse (red), Azimuth = 125deg, dip = -85 deg.

No topcut was applied to the data.
Sn, WO_3, Cu, Fe and density were estimated to the blocks using the following search parameters:

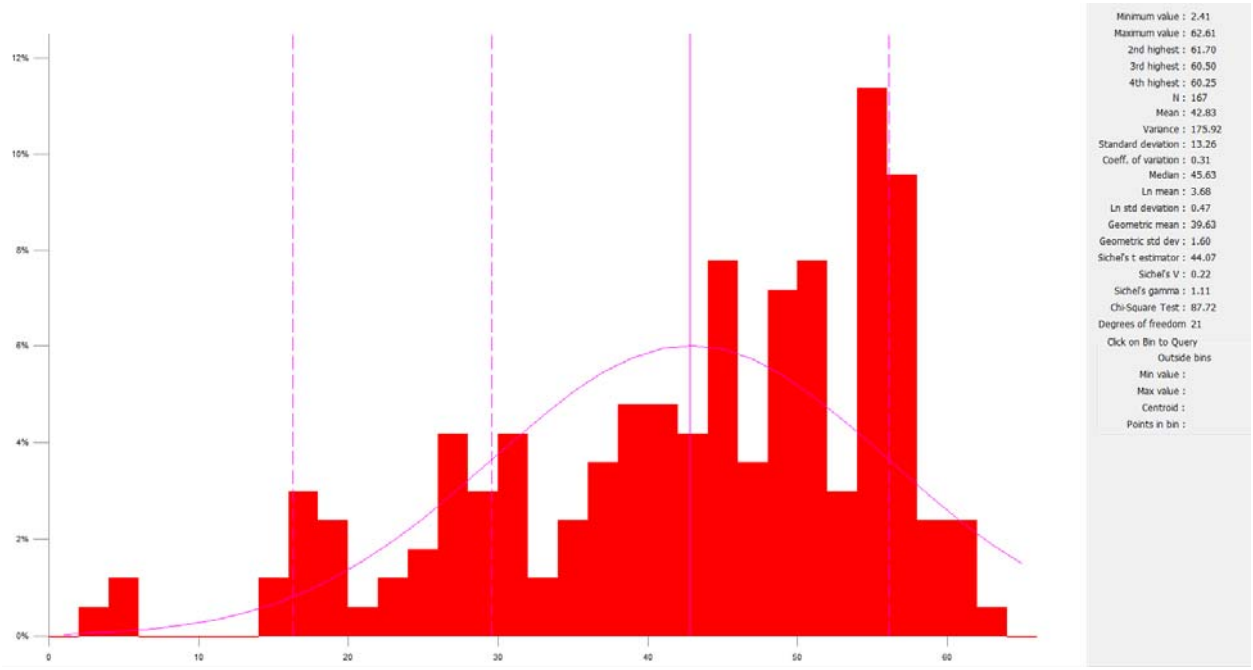

Figure 71: Summary statistics and histogram for composite Fe grades, Reward Skarn.

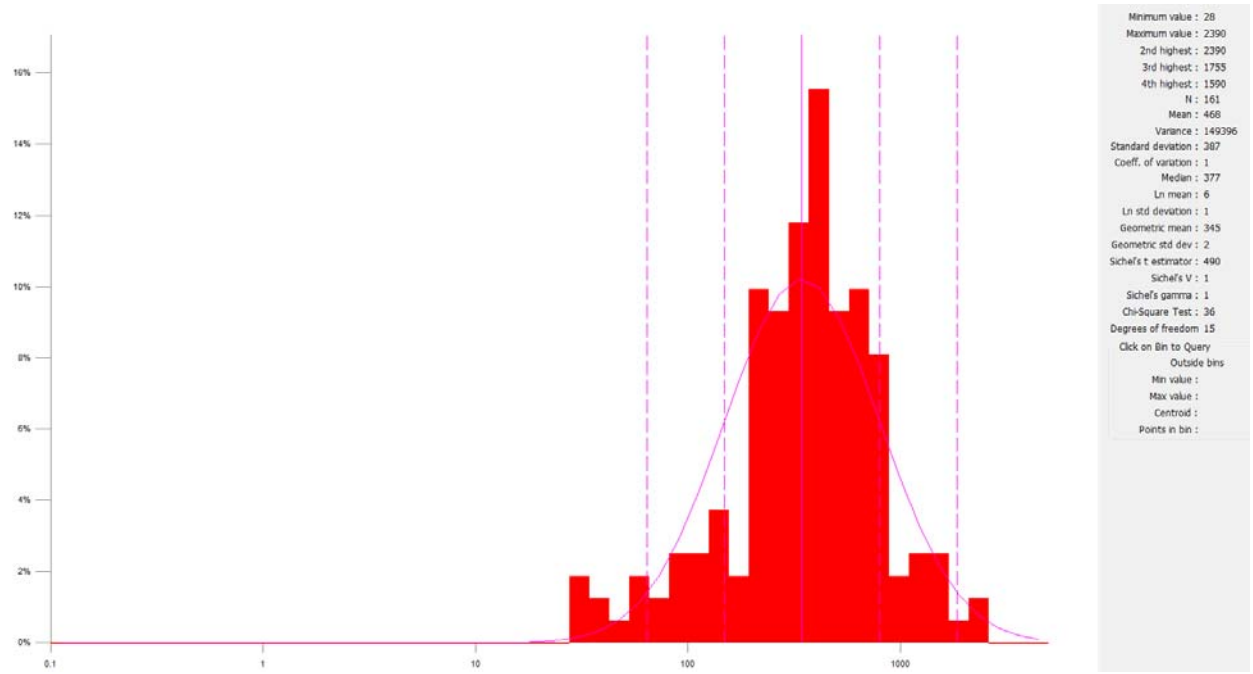

Figure 72: Summary statistics and log histogram for composite Cu grades, Reward Skarn.

8.3 Validations

The final model was graphically reviewed in Micromine. The model was colored by different attributes while cross sections and plans were generated. Drill holes were also overlain to check grade smoothing effects. Cross sections of the blockmodels coloured by SnEQ grade can be found in Appendices A (Main skarn), B (No.2 Skarn) and C (Reward Skarn).

Finally the models and corresponding composite drillhole assay files were exported into Excel and SWATH plots were created for all commoditied and the density, comparing average grades by easting. The validation plots can be found in Appendix D.

9 Estimated Resources

9.1 Classification

For the Main and No.2 Skarns, the classification of the Resources has been based on the variography run during the Ordinary Kriging estimation process for tungsten. Measured Resources are for continuous areas where the majority of blocks are estimated within the range of the variograms, and which coincide with high levels of data quality, quantity and confidence in the geological interpretation. Indicated Resources are for continuous areas where the majority of blocks are estimated within twice the range of the variograms, and which coincide with an appropriate level of data quality, quantity and confidence in the geological interpretation. All areas outside of the Measured and Indicated Resources have been classified as Inferred.

For Reward, the classification of the Resources has been based on the estimation run during the Inverse Distance Weighed estimation process. Indicated Resources are for continuous areas where the majority of blocks are estimated within the range of the minimum drill hole spacing and which coincide with higher levels of data quality, quantity and confidence in the geological interpretation. All areas outside of the Indicated Resources have been classified as Inferred.

9.2 Estimated Resources

Tonnages were estimated to fresh blocks by the Ordinary Kriging (for Main and No.2 Skarns) or Inverse Distance Weighting Squared method (for Reward skarn) using composited drill core densities. Clay zones were assigned a density of 1.7 t/m^3 and gossan zones 2.6 t/m^3 (see Section 4.4). The estimated Sn, WO_3, MR and Cu resources by deposit, category and SnEQ cut-offs is given in Table 10 (not rounded), and summarised in Table 1 (rounded) according to the prefered Sn Equivalent (SnEQ) cut-offs 0.20%, 0.35% and 0.45 SnEQ represents the combined values of co-products Sn, WO_3 and MR normalised to the value of Sn, and was calculated as follows: for Main and No.2 deposits SnEQ % = Sn % + (WO_3 % x 1.90459) + (MR % of magnetic Fe x 0.006510) + (Cu % x 0.28019); for the Reward deposit SnEQ % = Sn% + (WO3% x 1.65217) + (Cu% x 0.34783). The Sn equivalent formulae uses a tin metal price of US$23,000/t, an APT (Ammonium Para Tungstate) price of US$380/mtu (1mtu =10kgs of WO_3), a magnetite concentrate price of US$110/t and a copper metal price of US$8,000/t.

Table 28: Estimated Sn, WO_3, MR (magnetite) and Cu Resources for the Main, No.2, and Reward skarns using Sn Equivalent cut offs. Resources for the Main and No.2 skarns are by Ordinary Kriging and classified as Measured, Indicated and Inferred. Resources for the Reward skarn are by Inverse Distance Squared weighting and all classified as Indicated and Inferred.

Blockmodel coloured by SnEQ_%
Pit design = pd19cwf

Drill hole traces coloured by lithology:
black = magnetite skarn, magenta = sulphide skarn, yellow = qz-carbonate skarn, red brown = biotite skarn
green = amphibole & borate skarn, blue-green = garnet-vesuvianite skarn, pale blue = pyroxene microskarn
dark blue = marble & limestone, grey = lithic sandstone and siltstone, pink = granite, red = fault zone
pale brown = clay

1. METALLURGICAL TESTWORK OVERVIEW

1.1 Testwork Scope

To facilitate and progress the BFS, a detailed metallurgical testwork program was implemented. Tests were conducted through three major laboratories in Perth with specialist testing also conducted in laboratories based in Perth, Adelaide, Burnie, Gold Coast and Guangzhou, China. Testwork closely simulated the flowsheet proposed in the PFS with all unit processes being tested in sequence with expected process flows.

Prior to committing larger quantities of sample to testing, a significant amount of bench scale testing was conducted to confirm optimum operating conditions for each of the unit processes and also to make modifications to improve the flowsheet. The testwork was divided into two phases:

- **Phase 1** – for unit processes leading to production of "SRT" known as Sulphide Rougher Tail. This essentially covers crushing, grinding and classification, magnetic separation and sulphide flotation. This phase will also include testwork for production of a magnetite concentrate, chalcopyrite concentrate and a sulphide reject stream.

- **Phase 2** – for testwork to configure the flowsheet from the SRT stream for production of cassiterite concentrates and scheelite either as a concentrate and/or APT. The unit processes include a proprietary calcite and scheelite flotation process developed by Guangzhou Research Institute of Non-ferrous Metallurgy (GZRINM), an APT plant, gravity concentration and flotation of cassiterite. As per current industry practice, tin concentrates produced by gravity and flotation will be combined for sale to tin smelters.

1.2 Testwork Samples

In total, three tonnes of material was prepared for testing and covers the two main ore types and a blend.

The samples were used for the entire metallurgical program and comprise:

- 900 kg of MacDonald Zone (Main Skarn);
- 900 kg of Radford Zone (#2 Skarn);
- 1,200 kg of a 50:50 blend of MacDonald and Radford Zone ores.

The head grades of the three samples are presented in the following table. Please note that Arsenic (As) was inadvertently not assayed for the individual skarn samples. The reference made as "Ore Type 3" was the term the testing laboratory used for the 50:50 Blend sample.

Assays are in ppm unless otherwise noted

2. PHASE 1 TESTWORK

2.1 Overview

The majority of the Phase 1 metallurgical testwork was conducted at ALS Ammtec, Balcatta and established the conditions for primary grinding, rougher magnetic separation and bulk sulphide flotation (no differential flotation of chalcopyrite) to then produce SRT via pilot scale equipment. All products were collected for subsequent testing. The testwork flowsheet adopted is also shown on the following page.

The metallurgical testwork conducted included the following:

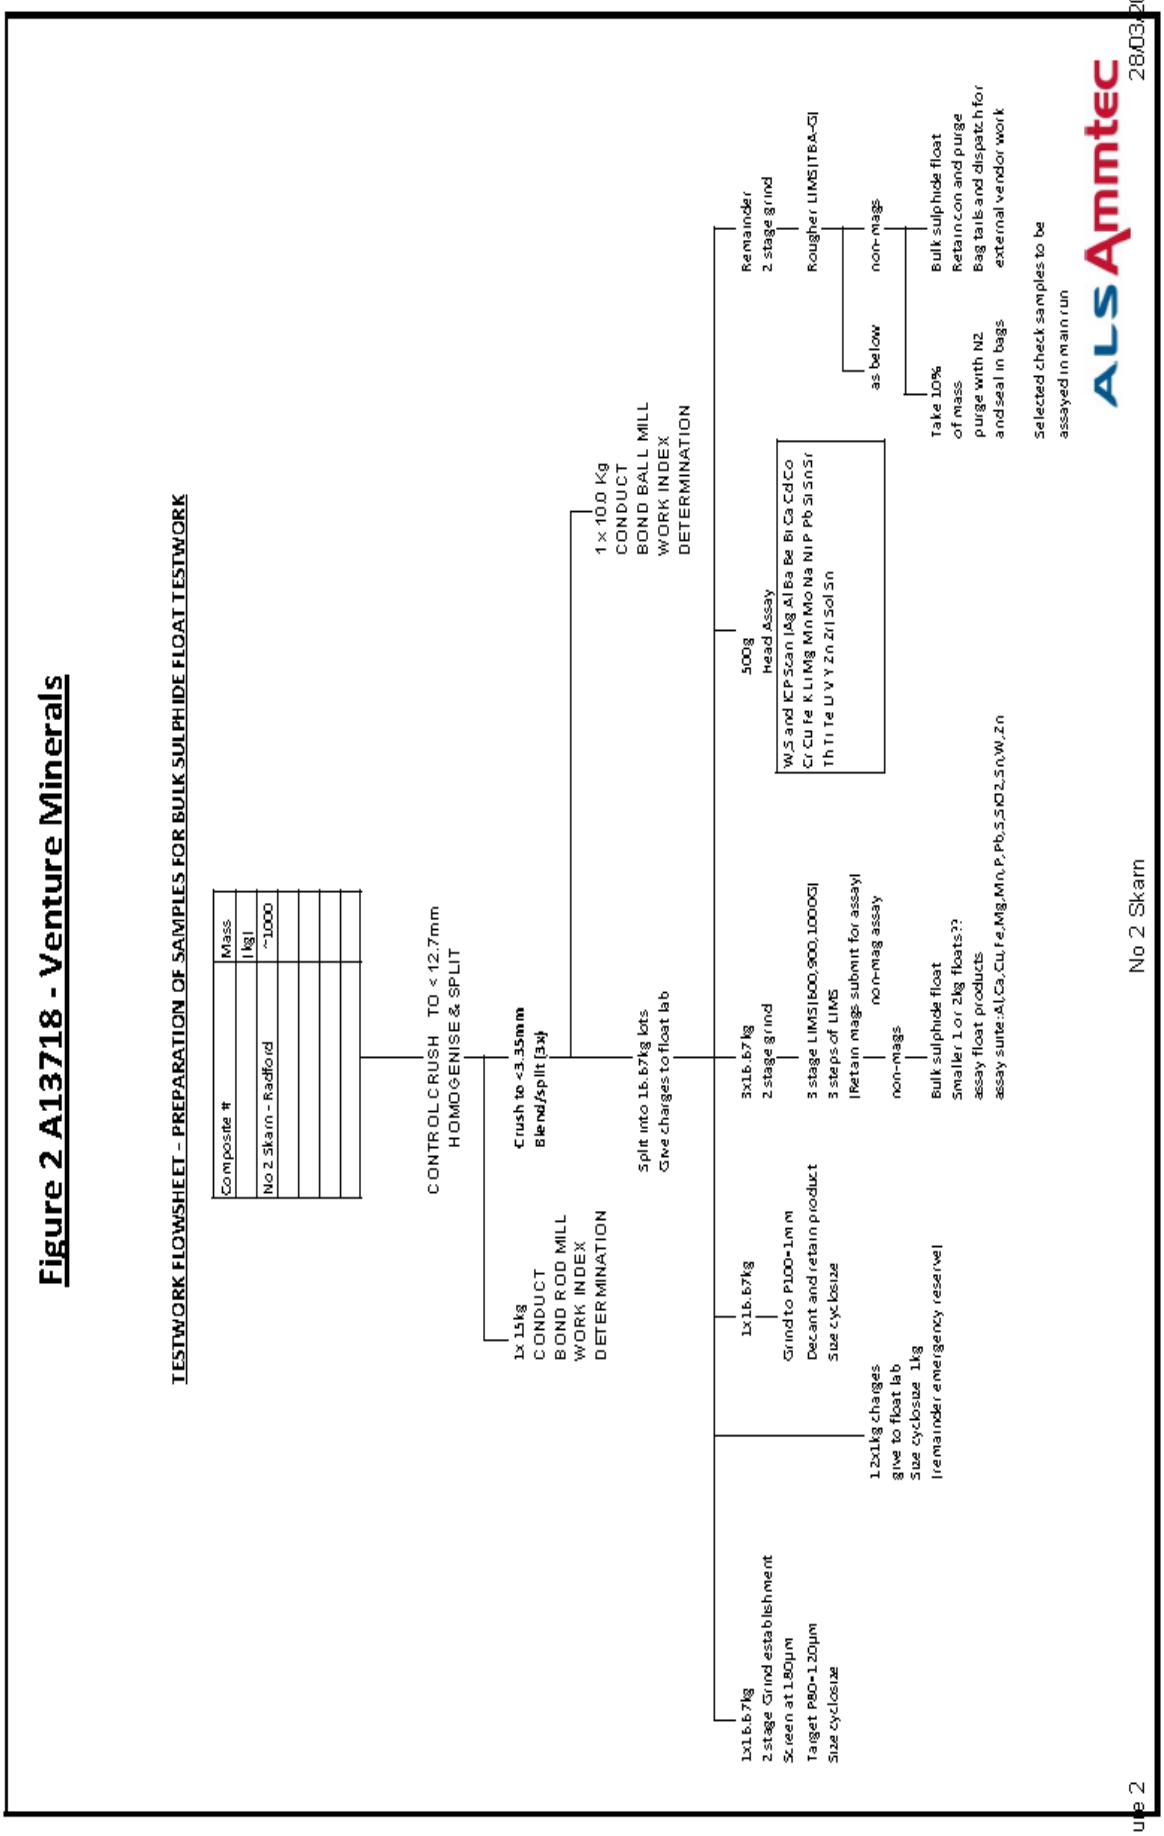
- Preparation and sub-sampling of two bulk composites (MacDonald Skarn and Radford Composites) to be treated in the pilot plant, with the sub-samples used for:
  - Head and size analysis;
  - Comminution testwork;
  - Sighter LIMS testwork; and
  - Base-line sulphide flotation testing.
- Pilot scale magnetic separation and sulphide flotation of each of the samples to produce magnetic and sulphide concentrates and low sulphide tailings for testwork to recover scheelite and cassiterite.

2.2 Primary Grinding

A key finding from the PFS was to establish an optimum primary grinding size of a P_{80} of 120-125µm. The nominal grinding size was also substantiated by mineralogical testing conducted in the PFS by W. Fander & Associates. The key findings were that generally, composites were sufficiently liberated at 130µm with some minor oxidation of pyrrhotite. On this basis, no re-examination of primary grind size was considered warranted.

The crushing and grinding circuit proposed for Venture is for ore to be initially crushed through primary and secondary crushers to a P_{95} of 20mm. Crushed ore is then fed to the grinding circuit where a rod mill and a ball mill will operate in conjunction with Derrick type screens to achieve the primary grind P_{80} of 125µm. The rod mill will be nominally designed to produce a -1.0mm product which is then fed to the ball mill.

The sizing and work index data generated from both MacDonald and Radford zones were provided to Bear Rock Solutions for modelling and simulating, at an Order of Magnitude level, a crushing and grinding circuit to treat 1.3Mt/a of ROM feed. Variation of Run-of-Mine top size from 600 to 1000mm and varying levels of fineness were included in the scope to provide some sensitivity for the selection of crushers. The variation in ROM size distribution did not appear to impact throughput or the ability to generate the required product size – providing the correct crushers were selected.



2.3 Primary Low Intensity Magnetic Separation (LIMS)

Sighter wet LIMS separation was carried out on each composite at the required primary grind size of P80 125µm. The initial tests were conducted at 600 Gauss (G) with the non-magnetics being re-passed at 900 G. Later tests also included a pass of the 900 G non-magnetics at 1000 G. All of the magnetic fractions and the final non-magnetics for each test were assayed in detail.

Consistent with the skarn mineralogy, the Radford Zone sample had a higher magnetic deportment (29%) compared to the MacDonald Zone (6%). Typically, the magnetic deportment from ROM feed for each skarn has ranged between 20-30% for #2 Skarn and 5-20% for Main Skarn. The inclusion of the 1000 G test was to provide a measure of the magnetic recovery efficiency. Data from the testwork conducted at ALS Ammtec would suggest that a magnetic recovery of >98.5% was being achieved at 900 G.

The above tests were undertaken using an Eriez L8 laboratory scale LIMS with a tank set up in a concurrent configuration which is in line with industry practice. From a mineralogical perspective, the magnetics fraction

also contains monoclinic (magnetic) pyrrhotite which will ultimately require separation by flotation from the magnetite to produce a saleable magnetite “concentrate for sale” (CFS).

2.4 Magnetic Regrind

Venture has signed a non-binding Memorandum of Understanding (MoU) with Grange Resources as a potential magnetite concentrate off-take party. This being the case, then it is important that Venture's concentrate satisfies Grange's pellet feed sizing specification of a P_{80} of 45µm for its Port Latta pelletising operation. Discussions with Grange personnel involved with the Southdown project highlighted that they are currently investigating the IsaMill developed and marketed by Xstrata Technology for the magnetic regrind duty.

The IsaMill can be accurately scaled up from laboratory sized testwork provided that the media and pulp conditions used are representative of that which will be used in the plant. Scale-up from testwork can then be done directly using the signature plots obtained.

The calculated specific energy at the desired grind size for the test samples were:

- 24.9 kWh/t for MacDonald Zone
- 23.2 kWh/t for Radford Zone

2.5 Cleaner Low Intensity Magnetic Separation

Following regrind, the magnetic concentrate is then reconcentrated through another stage of low intensity magnetic separators. In magnetite concentrators the normal practice is to use a magnetic separator in a counter-current configuration (also known as a Steffenson tank) with either two or three drums in series. The magnetics fraction undergoes repeated cleaning and the non-magnetics being rejected as tailings at each stage. However, a laboratory scaled magnetic separator was not available. The tests looked at optimum gauss settings at the regrind product size of P80 of 45µm in an identical manner to the primary LIMS tests detailed above.

Both series of tests reconfirmed that 900 to 1000 G as optimum for magnetite concentration. At a setting of 1000 G only an additional 1.5 and 1.2 weight percent of magnetics was recovered. However, the SiO_2 content increased to well above 4% which will increase again after the pyrrhotite flotation step.

2.6 Pyrrhotite Flotation

The final part of the magnetite process, before filtration of the concentrate, is a flotation step to remove the monoclinic (magnetic) pyrrhotite. If the magnetite concentrate is to be agglomerated by pelletising, the pyrrhotite produces sulphur dioxide fumes during induration. Sinter and pellet plants have strict emission tolerances on sulphur dioxide levels. Flotation is proposed to remove the pyrrhotite, but its removal from magnetite ores to satisfy the magnetite concentrate sulphur specification of less than 0.25% S is generally a difficult exercise. Knowledge gained from other magnetite producers or projects more advanced than Venture's also confirmed that this is the case and the difficulty in achieving the target spec should not be underestimated.

The general conditions for pyrrhotite flotation were well established in the 1950's. (REF: C.S. Chang et al, "Flotation Characteristics of Pyrrhotite with Xanthates", Transactions AIME: Mining Engineering, February 1954). This benchmark work concluded the following:

- Pyrrhotite in water tends to an equilibrium pH and that its surface can be stabilised by the abstraction of cupric ions;
- Amyl xanthate is superior to ethyl xanthate as a collector for pyrrhotite and staged addition of collector increases flotation recovery. Staged addition also generally results in less overall quantity of collector for equivalent recovery;
- Acid activation greatly increases the floatability of pyrrhotite. Pyrrhotite with potassium amyl xanthate has a critical pH of 4.5 (to 5.2) which corresponds roughly to the equilibrium pH obtained by aeration of a pulp containing pyrrhotite;
- Copper activation is of no particular advantage in pyrrhotite flotation beyond the critical pH.

Initial testwork was completed at SGS Lakefield Oretest and a flotation regime was undertaken where the objective was to produce a magnetite concentrate low in sulphur.

Testwork was completed to target the monoclinic magnetic pyrrhotite Fe_7S_8 species. Potassium amyl xanthate (PAX) was used as the collector where the longer chain length relates to a lower solubility and an increase in hydrophobicity, however, the longer chain length reduces selectivity. Copper sulphate was used as an activator to enhance the recovery of the slower floating pyrrhotite when in the lower pH range. W22 was used as the frother. Sulphuric acid was used to adjust the pH to 4.5 which is standard practice for pyrrhotite flotation.

Preliminary tests with 150 g/t PAX and 100 g/t $CuSO_4$ achieved a sulphur grade of 0.99%. Based on these results it was decided to increase the collector and activator dosages. By increasing the reagent dosages to 260 g/t PAX, 250 g/t $CuSO_4$ and by increasing the float time from 24 minutes to 32 minutes it was found that a sulphur grade of 0.44% can be achieved. Additional testwork will be undertaken to further reduce the sulphur levels in the final magnetite concentrate.

2.7 Magnetite Thickening and Filtration

The magnetite concentrate is thickened and filtered to produce a filter cake which contains approximately 5-10% moisture. Thickener testwork was conducted at Outotec on the final magnetite concentrate to assist with the design and sizing of a concentrate thickener. The main objectives were to determine:

- Flocculant type and dosage rate;
- Overflow clarity;
- Underflow density; and
- Underflow yield stress.

The flocculant screening tests were conducted in cylinders and all flocculants tested produced good settling characteristics and supernatant clarity. Magnafloc 336 was selected for use in the dynamic thickening bench scale tests. Magnafloc 336 is a high molecular weight polymer that has approximately 30% anionic charge.

Dynamic thickener testwork was completed in a 99mm diameter test rig complete with rakes to simulate thickener operation. The testwork showed that the magnetite concentrate can be successfully thickened. The optimised conditions demonstrated that a 1.5 $t/m^2/h$ flux rate with 20% solids feed density could achieve 77 to

80% solids underflow density with only 2 g/t flocculant to produce overflow clarity of less than 100 mg/L. The testwork showed at the current estimated feed rate of 40 t/h, a 6m diameter thickener would be required.

Filtration testwork was conducted at Outotec on the final magnetite concentrate to assist with the design and sizing of a filter. The main objectives were to determine:

- Appropriate filter technology;
- Filter cloth selection;
- Cake thickness;
- Maximum filtration capacity; and
- Moisture content of the cake.

The Ceramec leaf test unit and a Buchner funnel test were utilised. It was found that the Ceramec filtration technology can readily dewater the magnetite concentrate to below the target cake moisture content. Test results achieved a test filtration rate of 1931 kg/m^{2}h at 9.7% cake moisture. The belt filter technology achieved a test filtration rate of 846 kg/m^{2}h at 10.5% cake moisture.

2.8 Sulphide Flotation Testwork

The non-magnetic fractions from sighter LIMS testwork were submitted for bench scale sulphide flotation testwork. To expedite the testwork program for scheelite and cassiterite concentration, the tests were undertaken for a bulk sulphide flotation with no differential recovery of copper (chalcopyrite). Chalcopyrite testwork was scheduled to be part of a separate program using a feed sample collected from the sulphide flotation pilot scale run.

2.8.1 Bench Test Procedure – Rougher Flotation

Non-magnetic samples were subjected to standard bench scale flotation. The testing procedure included:

- The non-magnetic sample was transferred to a laboratory *Agitair* LA500 flotation machine (2.2-litre cell) and adjusted to a pulp density of approximately 35% solids (w/w). The tests were conducted using a machine speed of 1000 rpm unless otherwise stated.
- Slurry pH and the operating reference potential (ORP) for Eh were measured at each flotation stage.
- Reagents were added as per the agreed reagent scheme. Collector was added incrementally by syringe to the desired dosage. Frother was added in drops from an eye-dropper (one drop estimated at 12 g/t).
- Flotation air was introduced manually into the flotation cell to achieve the optimum froth – depending on the stage of the test. A scraper using a set pattern of approximately 10 strokes per minute removed froth manually.
- The flotation tests were conducted using the flowsheet, reagent scheme, conditioning times and froth removal times as shown in each results table.
- Each flotation product was filtered, dried and weighed before being submitted for analysis.

2.8.2 Test Results – MacDonald

Each flotation test was completed under the following flotation conditions:

- Test GWS0227 : 50 g/t Potassium Amyl Xanthate (PAX), 100 g/t SIBX, 150 g/t $CuSO_4$, 3 concentrates (collected after 3 minutes, 6 minutes and 12 minutes of cumulative elapsed time)
- Test GWS0230 : As per GWS0227, 6 concentrates (collected after 1 minute, 2 minutes, 4 minutes, 6 minutes, 9 minutes and 12 minutes of cumulative elapsed time)
- Test GWS0229 : 150 g/t PAX, 150 g/t $CuSO_4$
- Test GWS0245 : As per Test GWS0229, distilled water
- Test GWS0246 : 150 g/t PAX, 250 g/t $CuSO_4$
- Test GWS0247 : 250 g/t PAX, 250 g/t $CuSO_4$

The results from these tests have been summarised and are presented in the table below:

MacDONALD (Main Skarn) BENCH SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO_3		S	
		(%)	Distn (%)	(%)	Distn (%)	(%)	Distn (%)
227	91.1	0.53	97.2	0.22	96.8	2.11	51.7
230	91.5	0.57	97.6	0.22	97.1	2.09	47.6
229	91.5	0.56	97.6	0.23	97.0	1.90	45.9
245	90.0	0.54	97.0	-	-	2.20	47.1
246	87.4	0.54	95.7	-	-	2.18	48.7
247	84.9	0.57	95.0	-	-	1.36	30.0

WO_3 not assayed for in tests 245 - 247

The aim of the sighter tests was to determine the conditions which maximised recovery of sulphur (S) to the rougher concentrate whilst minimising the content of tin (Sn) and tungsten (WO_3). With regards to the tails (or Sulphide Rougher Tails as it will be known in the plant), a nominal S content target of <0.5% S was set as desired based on advice from tin and tungsten specialists and also accepted plant practice. The sighter tests only managed to achieve a sulphur grade down to 1.36%. On that basis it was decided to proceed to the pilot run and to increase the dosage of PAX to 350g/t feed.

2.8.3 Test Results – Radford

For the sample obtained from the Radford Zone (#2 Skarn), the same test procedure was used as for the MacDonald Zone. Each flotation test was completed under the following flotation conditions:

- Test GWS0348 : 250 g/t PAX, 250 g/t $CuSO_4$, 6 concentrates (collected after 1 minute, 2 minutes, 4 minutes, 6 minutes, 9 minutes and 12 minutes of cumulative elapsed time) which was used for all tests
- Test GWS0349 : 350 g/t PAX, 250 g/t $CuSO_4$
- Test GWS0350 : 150 g/t PAX, 150 g/t $CuSO_4$

The results from these tests have been summarised and are presented in the table below:

RADFORD (#2 Skarn) BENCH-SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO_3		S	
		(%)	Distn (%)	(%)	Distn (%)	(%)	Distn (%)
348	89.1	0.22	97.8	-	-	0.87	25.1
349	90.2	0.21	98.1	-	-	1.19	34.2
350	89.3	0.23	98.2	-	-	0.87	25.0

WO_3 not assayed

The aim of the above sighter tests was to determine the conditions which maximised recovery of sulphur (S) to the rougher concentrate whilst minimising the content of tin (Sn) and tungsten (WO_3). The sighter tests only managed to achieve a sulphur grade down to 0.87%. On that basis it was decided to proceed to the pilot run and using a dosage of PAX to 250g/t feed with the provision to increase to 350g/t should the pilot control assays indicate that more collector is required to be added.

2.8.4 Test Results – Blended Sample

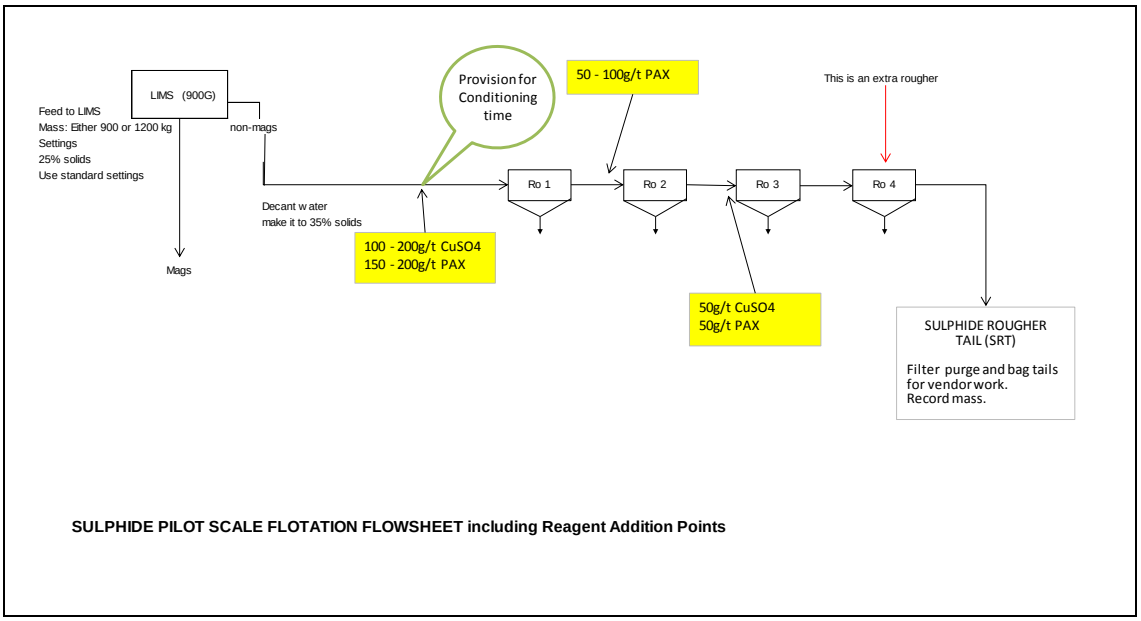
A blend prepared to the ratio of Main Skarn: #2 Skarn that is likely to be expected in the mine plan was also tested using the same test procedure as described above. Each flotation test was completed under the following flotation conditions:

- Test GWS0578 : 350 g/t PAX, 250 g/t $CuSO_4$, 6 concentrates (collected after 1 minute, 2 minutes, 4 minutes, 6 minutes, 9 minutes and 12 minutes of cumulative elapsed time) which was used for all tests
- Test GWS0579 : 250 g/t PAX, 250 g/t $CuSO_4$
- Test GWS0580 : 150 g/t PAX, 150 g/t $CuSO_4$

The results from these tests have been summarised and are presented in the table below:

BLENDED SKARN COMPOSITE BENCH SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO_3		S	
		(%)	Distn (%)	(%)	Distn (%)	(%)	Distn (%)
578	87.2	0.33	94.7	0.40	94.3	0.19	8.09
579	85.1	0.32	93.1	0.45	93.0	0.17	7.12
580	85.5	0.34	93.7	0.36	93.4	0.18	7.37

The aim of the above sighter tests was to determine the conditions which maximised recovery of sulphur (S) to the rougher concentrate whilst minimising the content of tin (Sn) and tungsten (WO_3). These tests produced the best results compared to the previous bench tests. Sulphur recovery to the rougher concentrate was over 92% with tin and tungsten minimised at 5-7%. On this basis it was decided to proceed to the pilot run and using a dosage of PAX to 250g/t feed with the provision to increase to 350g/t should the pilot control assays indicate that more collector is required to be added.



2.9 Sulphide Rougher Flotation Pilot Scale Testing

To process the bulk of the sample tonnages, pilot scale runs were undertaken. The samples had already been ground to the desired primary grind P80 as soon as the conditions were established. This was to facilitate proper sample division for all of the bench scale tests and to ensure that the results from those tests can be directly transferable to the pilot scale runs. The pilot runs therefore comprised of a wet low intensity magnetic separation followed by a bulk sulphide rougher flotation on the non-magnetics.

The primary magnetic fractions were designated for further development of a magnetite concentrate. The sulphide rougher concentrates will be subjected to concentrate cleaning tests and the Sulphide Rougher Tails (SRT) will be used for processes that concentrate scheelite and cassiterite.

The magnetic separator used was an Eriez L8 lab scale drum magnet. The setting, in line with previous tests which used the same piece of equipment, was 900 G.

A total of 12 minutes residence time was used in the bench scale flotation tests. A scale up factor of 2.5 was applied to size the pilot flotation cells so therefore a residence time of 30 minutes was used. The flotation cells recommended to use were “Agitair” type with a nominal cell volume of 15 litres. This size was suitable given the relatively small amount of sample that was available for a pilot scale test. A feed rate of 50 kg/h was used to give the correct solids content to the process. The cells were configured where the first two roughers were of a nominal volume of 15 litres each. The third roughers had two cells operating for a combined volume of 30 litres. The tests also included a fourth rougher for some extra capacity to ensure the integrity of the rougher tail generated in the case of any circuit interruptions up stream. The circuit configuration is presented as follows.

SULPHIDE PILOT SCALE FLOTATION FLOWSHEET including Reagent Addition Points

The results of the three pilot runs are summarised in the following tables. WO_3 was not assayed for in the Radford pilot tests.

Overall the tests were completed reasonably smoothly. The magnetics content of the MacDonald and Radford zone samples aligned with expectations. The magnetics content of the blended sample was higher than anticipated. However, the magnetic content of the two skarn zones does vary and the blended sample was considered to represent an upper end proportion of magnetic material.

The grade of the SRT stream also provides an indicator of the process performance quality. An acceptable level is for SRT <1.0% S with a preference for SRT <0.5% S. The two SRT's from the pilot plant were well below 1.0% S with one below 0.5% S.

2.10 Sulphide Cleaner Flotation Bench Scale Testing

A common flotation circuit usually includes a rougher/scavenger and a cleaner stage. The concept for incorporating a cleaner step is that it allows for a slightly higher mass pull to the rougher froth concentrate to maintain the desired SRT sulphur grade.

No testwork on cleaning of the sulphide rougher concentrate was undertaken during the PFS to fully delineate the design of the sulphide circuit. The issue that required solving is firstly to determine the number of cleaning stages and, depending on the results of initial cleaning tests and only if necessary, consider incorporating a staged regrind of the rougher concentrate prior to cleaner flotation. The rougher flotation concentrate can then be reground to increase the liberation before being fed to the cleaner flotation vessels.

As well as maximising sulphur recovery, the primary objective is to minimise losses of cassiterite and scheelite to the Final Sulphide Concentrate (FSC) which is discarded to the tailings storage facility. Cleaning tests were conducted on MacDonald and Radford zone material only as the blended skarn composite was still undergoing initial grinding, magnetic separation and sulphide rougher flotation testing.

2.10.1 Bench Test Procedure - Cleaner Flotation

Sulphide Rougher Concentrate samples of MacDonald and Radford zone material was subjected to standard bench scale flotation. The testing procedure included:

1. The rougher concentrate was transferred to a laboratory 2.5-litre cell and adjusted to a pulp density of approximately 35% solids (w/w). The tests were conducted using a machine speed of 800 rpm unless otherwise stated.
2. The tests were conducted at natural pH. Slurry pH and the operating reference potential (ORP) for Eh were measured at each flotation stage.
3. Reagents were added as per the agreed reagent scheme. Collector was added incrementally by syringe to the desired dosage. Frother was added in drops from an eye-dropper (one drop estimated at 12 g/t).
4. Flotation air was introduced manually into the flotation cell to achieve the optimum froth – depending on the stage of the test. A scraper using a set pattern of approximately 10 strokes per minute removed froth manually.
5. The flotation tests were conducted using the flowsheet, reagent scheme, conditioning times and froth removal times as shown in the results tables.
6. For tests that involved a second cleaner, the first cleaner concentrates were not individually assayed but recombined for second cleaner flotation testing.

Each flotation product was filtered, dried and weighed before being submitted for analysis. The residence time for first and second cleaner flotation tests were 8.5 minutes and 3.5 minutes respectively. The results of these tests are summarised in the following tables below:

MacDONALD CLEANER FLOTATION TESTWORK RESULTS - 2 Stage												
Product	Weight %	S		Fe		Cu		As		Sn		WO_3

Assuming that both cleaner tails are recycled back to the sulphide roughers, then from the above results the MacDonald tests there was a 50.5% mass recycle from two stages of cleaning as opposed to 43.0% from a single cleaning stage. The addition of a second cleaning step only reduced stage losses of Sn from 29.8% to 24.7% and for WO_3 from 15.5% to 7.6%. For the Radford tests, there was a 77.0% mass recycle in the first cleaner tail which increased to 82.6% with a second stage of cleaning. The addition of a second cleaning step reduced stage losses of Sn from 7.9% to 3.8% and for WO_3 from 8.9% to 2.8%. When taking the deportment of Sn and WO_3 to the rougher concentrate into consideration for the MacDonald testwork, the second cleaning stage has an overall effect on losses for Sn of only a reduction from 4.22% to 3.50% and for WO_3 a reduction of 1.35% to 0.43%. (Unfortunately, the testing laboratory did not request WO_3 assays for the Radford zone tests).

The interesting feature of this testwork was the results from the Radford zone material. Compared to the MacDonald zone tests, overall mass recovery and recovery of As, Fe (more particularly) and S to cleaner concentrates was significantly lower. It appears that for the Radford zone the flotation response of S and As is more difficult to achieve compared to MacDonald feed.

While the bulk sulphide rougher flotation tail grades on the primary non-magnetic stream achieved the S and As feed grade targets for scheelite and cassiterite concentration, the slower S and As response became more noticeable in the sulphide cleaning circuit for Radford zone material. This is also supported by the lower mass recovery to the cleaner concentrates.

The problem is suspected to be caused by the presence of the mineral Lollingite, an iron arsenide ($FeAs_2$). Venture geologists have also indicated to be aware of the presence of Lollingite which is more prevalent in the Radford zone compared to the MacDonald zone. Further details on this mineral are available through the following link, http://webmineral.com/data/Lollingite.shtml

Lollingite is often associated with arsenopyrite (FeAsS). The two minerals are generally difficult to distinguish from one another. When viewed closely under polarizing microscopes, the two minerals are exhibiting similar crystal forms, colours, streak, lustre and fracture. The only slight difference is that Lollingite is somewhat denser and softer. Most base metal mines with an arsenide problem responds by trying to suppress it, so there is plentiful information on testwork that aims to suppress arsenides. The Venture Minerals flowsheet requires it to be activated and removed as part of the sulphide flotation concentrate which is deposited into a tailings storage facility. Fortunately, it appears that Lollingite generally behaves similar to arsenopyrite unlike other more complex arsenides found on the Tasmanian West Coast.

So following from the above, an additional series of bench scale tests were undertaken for single stage concentrate cleaning with reagent dosages at similar levels to the rougher flotation. The following conditions were used:

- 250 g/t PAX, 250 g/t $CuSO_4$, 4 concentrates (collected after 1 minute, 1 minute, 2 minutes and 5 minutes for a total of 9 minutes cumulative elapsed time). All of the flotation tests were still conducted at natural pH.

A summary of the results are presented in the following tables:

The increased reagent dosage has resulted in a marked improvement in mass recovery and deportment of S, Fe and As to cleaner concentrate. Losses of Sn and WO_3 have also been maintained at similar levels to the previous set of testwork. Arsenic stage recovery has improved to 92% and 65% for MacDonald and Radford zones respectively from 84% and 32%. Sulphur stage recovery has shown similar improvements to 95% and 76% for MacDonald and Radford zones respectively from 91% and 44%. The grades of the first cleaner tails recirculating back to the head of the sulphide rougher flotation circuit are acceptable.

Overall the tests have demonstrated that a single cleaning stage is required without the need for regrinding sulphide rougher concentrate. The cleaner tail stream can recirculate back to the head of the sulphide rougher flotation cells. Losses of Sn and WO_3 are low by industry standards. Renison, for example, has Sn losses of between 7 and 12% to the final sulphide concentrate. Sn losses have been demonstrated to be in the order of 3.5%. WO_3 losses have been consistently below 1.5% for all tests.

2.11 Copper Flotation Bench Scale Testing

The non-magnetic fractions from sighter LIMS testwork were used to evaluate the potential to recover a copper concentrate product. It is proposed that the removal of the chalcopyrite as a copper flotation rougher concentrate occurs prior to sulphide flotation. Sulphide flotation is followed by the calcium float for the separation of scheelite, fluorite and calcite from cassiterite.

Preliminary testwork indicated that most of the copper would report to the non-magnetic fraction. This confirms mineralogy reports that the copper is liberated at the current grind size and not associated with the magnetic minerals.

Testwork has been completed and it has shown that it is possible to achieve an upgrade from the copper rougher concentrate from 0.08% Cu to 1.94% Cu.

2.11.1 Bench Test Procedure - Copper Flotation

The non-magnetic stream copper flotation samples were subjected to standard bench scale flotation and the testing procedure included:

- The non-magnetic fraction copper flotation samples were transferred to a laboratory 2.5-litre cell and adjusted to a pulp density of approximately 35% solids (w/w). The tests were conducted using a machine speed of 900 rpm unless otherwise stated.
- The tests were conducted at natural pH. Slurry pH and the operating reference potential (ORP) for Eh were measured at each flotation stage.
- Reagents were added as per the agreed reagent scheme. Collector was added incrementally by syringe to the desired dosage. Frother was added in drops from an eye-dropper (one drop estimated at 12 g/t).
- Flotation air was introduced manually into the flotation cell to achieve the optimum froth – depending on the stage of the test. A scraper using a set pattern of approximately 10 strokes per minute removed the froth manually.

Each flotation product was filtered, dried and weighed before being submitted for analysis. Initial tests produced a 1.94% copper rougher concentrate at approximately a 65% stage recovery. This was achieved in 3 minutes flotation time using a dithiophosphate collector which recovered approximately 6% mass to copper concentrate.

However to achieve the cleaner result pH was adjusted to approximately 8 to 9. Copper grade increased from 1.94% to 5.69% in a single cleaning stage. Testwork is currently being completed to increase the copper grade and achieve a saleable product. It is envisaged that another three to four stages of cleaning is likely to be required.

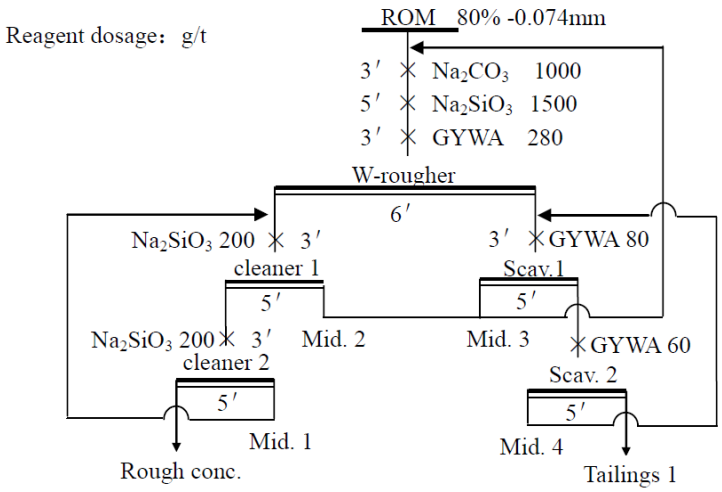
3 PHASE 2 TESTWORK

3.1 Confirmatory Calcite/Scheelite Flotation Testwork

As indicated above, the intent of the Phase 2 testwork is to utilise the results generated for configuring the flowsheet from the SRT stream onwards for production of cassiterite concentrates and scheelite either as a concentrate and/or APT. During the PFS, some scoping type studies were conducted at GZRINM where they have developed proprietary reagents for calcite and scheelite flotation. These results were very encouraging as the process indicated the potential to produce a high WO_3 recovery, high grade tungsten concentrate with excellent selectivity that minimises losses of cassiterite to the calcite/scheelite concentrates.

Because testwork conducted at GZRINM was very limited but the results obtained were extremely promising, some additional confirmatory testwork was conducted at ALS Ammtec's laboratory in Burnie, Tasmania in December 2011. The professor responsible for the GZRINM testwork, Professor Zhang Zhonghan, visited Burnie with samples of the proprietary reagents GYW and GYW-A.

Samples of SRT material produced from the sulphide flotation pilot plant of Main Skarn and #2 Skarn were provided. A 50:50 blend of the two skarns was also composed at the laboratory. The assays for the primary skarn samples are presented in the following table. The assays also reconfirm that the sulphide rougher flotation was undertaken to an acceptable level.



Element (%)	WO_3	Sn	Fe	Mo	Ca	SiO_2	MgO	Mn	As	S	Cu	Al
Main Skarn	0.19	0.42	19.80	<0.01	7.95	32.60	2.91	0.30	0.11	0.35	0.03	4.06
#2 Skarn	0.48	0.20	20.10	<0.01	7.65	35.20	2.37	0.30	0.11	0.49	0.02	4.25

As for the scheelite flotation operation, the test results achieved in Burnie were a little better than the initial tests conducted in Guangzhou. The rougher flowsheet is relatively simple which assists in achieving good results. Tests were conducted initially on a batch basis to scout and optimize reagent additions. The conditions that produced the better results in terms of grade and recovery were then used in locked cycle tests. The rougher concentrate has a high recovery of scheelite as well as calcite, which has downstream benefits for the processing of cassiterite. Cassiterite losses, in terms of the quantity reporting to the rougher concentrate, are very low. The scouting results also indicated that reagent GYW-A performed better than reagent GYW. Both reagents are modified fatty (oleic) acids, but GYW-A represents a slight modification to GYW on the basis of the tests conducted in the PFS.

The locked cycle results are presented in the following table:

Product	Weight, %	Assay,%			Distribution,%		
		WO_3	Sn	Ca	WO_3	Sn	Ca
Concentrate	7.49	4.07	0.06	25.90	92.95	1.50	26.10
Tail	92.51	0.025	0.32	5.94	7.05	98.50	73.90
Total (Calculated)	100.00	0.328	0.301	7.44	100.00	100.00	100.00

The locked cycle flowsheet and reagent additions are depicted as follows:

Only limited tests could be conducted on the heated cleaning stage. However, the best result achieved a final scheelite concentrate assaying WO_3 61.46% with a stage recovery of WO_3 76.90%. This result gave confidence that final concentrate grades over WO_3 65% are likely to be produced if three to five stages of heated cleaning are conducted. Scheelite recovery is expected to be higher than these initial tests.

Overall results achieved were very encouraging despite the limited time and sample quantities. The tests provided valuable data for when more comprehensive testing is conducted using the SRT produced from the pilot tests.

3.2 Other Confirmatory Testwork

3.2.1 Superpanning and High Gradient Magnetic Separation of Calcium Rougher Flotation Tail

The two main ore bodies at Mt. Lindsay were blended with equal amounts of Sulphide Rougher Tail (SRT) generated from the Radford and MacDonald Zone. This sample was subjected to superpanning and high gradient magnetic separation. A sizing analysis on the sample used in the tests confirmed the primary grinding sizing was 80% passing 122µm.

The test sample was prepared by initially taking about 600g each of both the MacDonald and Radford Skarns. The samples were carefully blended by back riffling five times. Then about 100g was riffled out as an assay head sample and another 100g was sized down to <5µm on a size by size basis. The remaining 1,000g was then screened on a size by size basis down to 38µm and the >38µm fractions were each subjected to magnetic separation on a dry "Rapid" cross belt magnet at about 3,000 Gauss and then 8,000 Gauss. The material was fed slowly to reduce entrainment. Only the >38µm Non-magnetic fractions were superpanned.

The testwork results are summarised in the following table:

Overall Summary								
Venture Blend(80% <122µm)		Assay				Distribution%		
<150µm &> 38µmm Processed	Wt%	Sn%	WO3%	Fe%	S%	Sn	WO3

N.M Comb. S.Pan Conc.	1.54	13.35	19.8	58.0	87.4	0.4	74.4	
N.M Comb. S.Pan S.Pan Tails	6.38	0.03	0.03	0.6	0.6	1.0	0.4	
Comb. Mags	92.08	0.16	0.06	41.4	12.0	98.6	25.2	
<150µm> 38µm Comb. Fractions	100.00	NA	NA	100.0	100.0	100.0	100.0	

Results from this testwork indicated that:

1. Up to 90% of the blended SRT is paramagnetic;
2. About 20% of the tin occurs as acid soluble tin (vonsenite) most of which reports to the paramagnetic fraction;
3. Scheelite recovery to the non-magnetic stream was very high at about 90% on the superpanning size fractions processed;
4. If a magnetic intensity of 3,000 Gauss (G) is used instead of 8,000 G, the weight rejection to the paramagnetic fraction is reduced from approximately 92% to 72% and tin losses are reduced from about 8% to 4%;
5. Superpanning indicated that cassiterite recovery on the SRT by conventional gravity separation is predicted to be between 40% and 45% to a high-grade concentrate.

Essentially, these tests concluded that at the primary grind size, 41% of the tin and 50% of the tungsten reported to the superpan concentrate. It can also be seen within the >38µm fractions that 92% of the SRT is paramagnetic and about 88% of the tungsten and only 58 % of the tin reported to the non-magnetics.

On the basis of these tests, additional testing of High Gradient Magnetic Separation was planned.

3.2.2 Alternative Scheelite Flotation on Sulphide Rougher Tail

An alternative approach to the whole ore flotation process developed by GZRINM was tested under the direction of Mr Kwang-Ho Ok. Mr Ok is a Metallurgist who was previously employed by King Island Scheelite and also worked on the Sandong scheelite mine in South Korea. A portion of SRT was provided for him to test at his discretion.

Flotation experiments were performed in a Lab Agitair flotation machine with a cell volume of 3.8 litres. For each test, approximately 1700g of the ore was transferred to the flotation machine cell. The pulp density was adjusted to ~40 % solids, while the conditioning with PAX and Dowfroth 400 for a time of 5 minutes was undertaken to perform a sulphide scavenging flotation. After conditioning, the pulp was diluted to ~30% solids. The scavenging sulphide was repeated in 5 stages aimed at total rejection to make it possible for scheelite flotation to be conducted. The sulphide froth products were combined in one tray and flocculated, filtered and dried for assay.

The tailings samples produced from the sulphide flotation were then processed for flotation of scheelite. The head samples, post sulphide scavenging flotation, assayed 0.7- 0.9% WO_3 range with 2.9% CO_2 (corresponding to 6.7 % $CaCO_3$). In comparison the feed grade of the blended skarn sample was 0.34% WO_3, 12% Ca and 20% Fe. During conventional processing using an initial rougher, scavenger and cleaner circuit, the scheelite flotation concentrate was upgraded to 15 -20 % WO_3 with ease by adjusting pH, using an oleic acid collector, sodium silicate and other calcite depressants such as Quebracho (70 % Tannic Acid).
The initial results indicated that upgrading to a 40% WO_3 (target) with reasonable recoveries by the conventional process was considered to be difficult due to the dilution of the froth concentrate by calcite and slime coating (particles of size < 15µm). In an attempt to improve selectivity of scheelite, ferrous sulphate as an iron salt was used in combination with sodium silicate and Quebracho. The resultant grade was still significantly lower than anticipated possibly due to the prior activation of calcium being hard to suppress.

The reagents used in scheelite flotation were as follows:

- Soda Ash as pH modifier
- N - Grade Sodium Silicate as siliceous gangue minerals depressant
- Quebracho for calcite depression, shown as RTD1027
- Oleic Acid, this collector is shown as V-1 Collector
- Di-octyl Sodium Sulfosuccinate, shown as A-OT
- Kerosene
- Caustic Soda

- Distilled water

The typical reagent schedule and flotation conditions used in these tests are listed in the following table:

	pH	10.0 H2S04 g/t	5.0 PAX g/t	100.0 Dow 400 g/t	10.0 Soda Ash g/t	14.63 Silicate g/t	5.0 RTD1027 g/t	2.0 Fe g/t	2.0 NaHS g/t	1.0 A-OT g/t	9.14 V-1 g/t	Temp g/t	Cond Time min	Air L/min	Float Time min	Cum Float Time	Wet Wt g	Con % Solids

Overall, the general comments and conclusions that were drawn from this testwork indicated that flotation of scheelite from calcite, fluorite and other skarn minerals was revealed to be less selective than expected and possibly due to a higher presence of fine slimes (particles of size < 15µm) than accustomed. It was therefore essential that multiple sulphide scavenging was included to make scheelite flotation possible. The best result for scheelite flotation achieved was a rougher concentrate grade of 25.5% WO_3 at a calculated recovery of 87 %. The rougher grade was below the target grade of 40% WO_3.

The major reason for lower than target grade being achieved was due to the presence of a large amount of calcite. Additional WO_3 grade improvement can be obtained by using an increased dosage level of Quebracho with modifying reagents such as sodium polyphosphate and sodium hexametaphosphate.

Two possible solutions to improve the metallurgical performance were given. To improve flotation performance further, selective grinding (or stage grinding) could be considered to minimize the generation of fine slimes. A P_{80} passing size of about 150-160µm was suggested. Also it was suggested to reduce the amount of undesirable weakly magnetic skarn minerals ahead of the sulphide flotation or the scheelite flotation step could

be beneficial to the overall flowsheet. It was suggested to investigate a high intensity wet magnetic separation step after primary low intensity magnetic separation.

Overall, the process being considered by Mr Ok was demonstrated to be more sensitive to the presence of slime than the GZRINM process. The GZRINM process also maximises recovery of calcite as well as scheelite. Recovery of calcite at this stage has potential downstream benefits for cassiterite recovery.

3.2.3 High Gradient Magnetic Separation (HGMS)

The superpanning tests conducted on the Sulphide Rougher Tail (SRT) and the Calcite Flotation Tail indicated a high mass proportion, up to 90% by weight, of paramagnetic material associated with the amphiboles is present in these streams. The results indicated that a high gradient magnetic step after sulphide flotation could be considered for inclusion into the flowsheet. A significant advantage if HGMS could be proven is that the mass-flow rates to the calcite/scheelite flotation circuit and the primary gravity circuit are dramatically reduced.

To investigate this process option scoping tests were conducted on a SLon 100 at Allied Mineral Laboratories (AML). The SLon 100 is a bench scale sized, vertically pulsating high-gradient magnetic separator that utilises a combination of magnetic force, pulsating fluid and gravity to continuously process relatively fine magnetic mineral slurries.

Preliminary results from the SLon 100 batch unit were quite encouraging with 82.3% of the mass reporting to the magnetic fraction. Based on the results achieved it was decided to complete testwork on a larger scale utilising a SLon 500 continuous pilot unit. This work was completed at Amdel Mineral Laboratories. Initial tests showed that recoveries of 60% to the magnetic fraction could be achieved. Scheelite fluoresces under shortwave ultraviolet light and initial investigations showed scheelite to be prevalent in both the magnetic and non-magnetic fractions. Even though the superpanning and RAPID tests showed the benefits of a high gradient magnetic step after sulphide flotation wet magnetic separation did not follow the dry magnet performance.

Further investigations were carried out with WHIMS (Wet High Intensity Magnetic Separator) at Amdel Mineral Laboratories to verify the results obtained from the SLon 500 and establish if there is any possibility of concentration and separation of the paramagnetic material. Although the efficiency of the WHIMS is below that of dry magnets from a processing point of view it can only work in a wet environment.

The testwork, presented in the following table, quite clearly supported the performance achieved in the SLon 500 and there was no upgrade in either the scheelite or tin grades. At this stage of the program, it was decided to eliminate the use of HGMS into the flowsheet. This does not preclude its use being reconsidered into the flowsheet at a later date.

3.3 Testwork Conducted at Guangzhou Research Institute of Non-ferrous Metallurgy (GZRINM)

3.3.1 Background

Coarse-grained scheelite is generally recovered by means of gravity separation while finer-grained particles are recovered primarily by flotation. As the feed samples have already been ground to a P80 of 120µm and magnetite and sulphide minerals have been recovered by LIMS and flotation respectively, the scheelite minerals in the ore are therefore suitable to be recovered by flotation.

The preferred collectors for scheelite flotation are mainly fatty acids or a modified fatty acid. Gangue minerals bearing calcium such as calcite, fluorite, diopside, garnet and other gangue minerals such as biotite and amphibole also have good floatability with fatty acids. The new reagent GYW-A developed by GZRINM is used as a scheelite flotation collector and replaces sodium oleate collector which has a poorer selectivity and higher consumption than GYWA. Reagents used as regulators/modifiers are generally used in combinations such as sodium carbonate / sodium silicate, caustic soda / sodium silicate, sodium carbonate / caustic soda /sodium silicate and sodium carbonate / lime /sodium silicate. The combined regulator of sodium carbonate /sodium silicate is adopted by GZRINM in the scheelite roughing process.

The rougher concentrate of scheelite flotation still contains a significant quantity of calcium bearing gangue minerals due to their good floatability with fatty acid type collectors. Since the floatability of calcium bearing gangue minerals with fatty acids is similar to that of scheelite the cleaning separation becomes very difficult. One method used for cleaning is the “Petrov Method”. This method relies on strong agitation conditioning of the pulp at high density with a large amount of sodium silicate added at an elevated temperature (normally 90oC). The heated pulp is dewatered several times prior to being sent for further flotation. For some scheelite ores, this method is not suited so GZRINM have developed new measures such as modifying sodium silicate and maintaining the elevated temperature for a period of up to 60 minutes, without dewatering, to then being able to directly float the scheelite from heated pulp.

3.3.2 Testwork Scope

GZRINM received Sulphide Rougher Tail (SRT) samples of Main Skarn and #2 Skarn that were produced from the pilot rougher flotation tests conducted at ALS Ammtec in Perth. The overall intent of the testwork was to build on the findings of tests undertaken in the PFS and also the scoping tests conducted at ALS Ammtec in Burnie in November 2011.

The objective was to develop a flowsheet that maximises grade and recovery of scheelite and minimises losses of cassiterite. The scope also included testing the potential of HGMS and WHIMS for removal of paramagnetic material and also including some coarse classification and primary spiral tests to generate samples to investigate fine calcite/scheelite recovery ahead of tin flotation.

A summary of results of the HGMS testwork have been reported elsewhere in this document. The conclusion was consistent with all other tests undertaken. A less than satisfactory performance was achieved as the losses of scheelite and cassiterite to the magnetics fraction were significantly higher than expected. This then

essentially meant that the testwork only considered flotation and the gravity separation and regrind processes only.

The tests involved two parts. The first part required keeping the skarn test samples in their separate ore types. The testwork completed on separate skarn ore types included primary calcite flotation, coarse classification, primary gravity concentration, gravity regrind and secondary (fine) calcite flotation. For the second part of the testing program, the calcite flotation rougher concentrates generated from each skarn were combined together for investigating the scheelite flotation circuit. This was done to ensure that sufficient material became available for a final product. Some minor bench scale tests were still completed to understand scheelite flotation of both ore types. The gravity spiral concentrates and middlings streams were consigned to CPG Mineral Technologies, Queensland for gravity testing. The secondary calcite flotation tail was returned to BV Amdel, Perth for tin flotation and other associated testing.

3.3.2.1 Feed Sample Analysis

A sizing, chemical and mineralogical analysis was initially completed on the samples received from Australia. The following table shows the particle size distribution of the calcite flotation feed together with size fraction chemicals for WO3 and Sn. Scheelite and cassiterite are distributed across the entire particle size range but predominantly contained in the finer size fraction below 30µm. An advantage of this flotation process is that it is a "whole ore flotation" process and does not require any hydrocycloning for removal of ultrafine particles prior to flotation.

Size (µm)	Main Skarn					#2 Skarn				
	Dry Weight (%)	Assay (%)		Distribution (%)		Dry Weight (%)	Assay (%)		Distribution (%)	
		WO_3	Sn	WO_3	Sn		WO_3	Sn	WO_3	Sn
100	29.58	0.11	0.35	15.47	21.30	26.85	0.33	0.30	16.04	34.75
75	1.29	0.16	0.49	0.98	1.42	1.41	0.42	0.25	1.07	1.52

-30	38.94	0.25	0.44	46.29	38.56	37.45	0.64	0.16	43.42	25.87
Total	100.00	0.21	0.44	100.00	100.00	100.00	0.45	0.23	100.00	100.00

Mineralogical examinations were completed at various stages of the program. The distribution of the main economic minerals for tin and tungsten identified in the samples used in the testwork are highlighted in the following table. For this initial work it is suspected that the use of "stannite" has been loosely used to indicate the proportion of soluble tin contained within the ore types. The proportions identified are consistent with estimates of soluble tin recorded from previous testwork conducted in other laboratories.

Mineral	Main Skarn		#2 Skarn	
	Content (%)	Distribution (%)	Content (%)	Distribution (%)
Cassiterite	0.37	80.43	0.16	72.73
Stannite (*)	0.09	19.57	0.06	27.27
Total of Sn	0.46	100.00	0.22	100.00
Scheelite	0.18	89.02	0.5	97.54
Wolframite	0.02	9.89	0.01	1.95
Tungstite	0.0022	1.09	0.0026	0.51
Total of WO_3	0.2022	100.00	0.5126	100.00

* - "Stannite" used to describe acid-soluble tin.

3.3.3 Primary Calcite Flotation

The major task of primary calcite rougher and cleaner flotation is to float out most of the scheelite and calcite as well as fluorite and meanwhile to keep the majority of tin minerals in the tailings. Flotation of calcite and scheelite from the ore will then create more favorable conditions for the recovery of the tin minerals.

The methodology is to work through various scenarios of dosage rates of sodium silicate, soda ash and caustic and sodium silicate and reagent GYW-A. Then once the conditions have been established, locked cycle testing for primary calcite flotation is completed. The results are summarised below in the following table. The results of these tests are acceptable, with high scheelite grade and recovery being achieved with minimal tin losses to the concentrate.

Product	Wt (%)	Sn		WO_3	
		%	Dist'n (%)	%	Dist'n (%)
Main Skarn					
Primary Calcite First Cleaner Con	7.48	0.15	2.37	2.57	86.65
Primary Calcite Second Scavenger Tail	92.52	0.50	97.63	0.03	13.35
Primary Calcite Flotation Feed	100.00	0.47	100.00	0.22	100.00
No. 2 Skarn					
Primary Calcite First Cleaner Con	8.89	0.14	3.83	5.38	93.75
Primary Calcite Second Scavenger Tail	91.11	0.26	96.17	0.04	6.25
Primary Calcite Flotation Feed	100.00	0.25	100.00	0.51	100.00

3.3.4 Scheelite Flotation

The concentrates from the primary calcite flotation tests were used as the feed for scheelite rougher flotation; the objective being to maximize rejection of calcite and fluorite to upgrade scheelite prior to the subsequent scheelite cleaner flotation step. The main outcomes are summarised below. The reagent additions and dosage points along with other test conditions from these particular tests have been included in the process design criteria.

Product	Wt (%)	Sn		WO3	
		%	Dist'n (%)	%	Dist'n (%)
Main Skarn					
Scheelite Rougher Con	85.15	0.12	68.94	3.01	99.69
Scheelite Rougher Tail	14.85	0.31	31.06	0.05	0.31
Scheelite Rougher Flotation Feed	100.00	0.15	100.00	2.57	100.00
No. 2 Skarn					
Scheelite Rougher Con	89.64	0.14	90.31	5.96	99.29
Scheelite Rougher Tail	10.36	0.13	9.69	0.37	0.71
Scheelite Rougher Flotation Feed	100.00	0.14	100.00	5.38	100.00

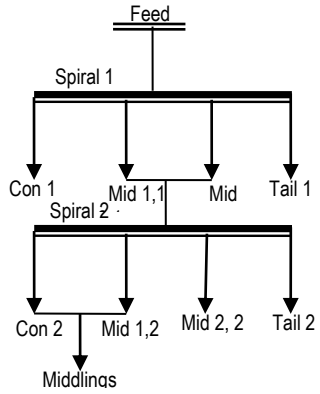
It is noted that whilst scheelite recovery to the concentrate was excellent for both samples only minor upgrades in scheelite concentrate grade were achieved in the scheelite rougher flotation stage. Selectivity of the tin minerals was virtually non-existent for # 2 Skarn and some selectivity apparent for the Main Skarn sample.

The scheelite rougher concentrates are thickened to a pulp density of 65% solids and then fed to the "heated" scheelite flotation process. GZRINM have modified the "Petrov Method" through such things as modifying sodium silicate and adding the modified sodium silicate mixture to enhance the depression of sodium silicate on calcium and sulphide gangue bearing which also increases the selectivity and recovery of scheelite. This process involves heavy agitation of the slurry whilst heating to 90oC and maintaining the slurry at that temperature for 60 minutes. This breaks down the residual reagents present in the scheelite rougher concentrate to provide "fresh" slurry to which reagents can be added as required without residual or excess reagents from the previous flotation steps impacting on performance.

Locked cycle flotation testing was completed on the samples after the attritioning stage was completed and the results are summarised in the following table. The reagent additions and dosage points along with other test conditions from these particular tests were included in the process design criteria. The final grades produced from this testwork are indicative of scheelite concentrate for sale.

Product	Wt (%)	Sn		WO_3	
		%	Dist'n (%)	%	Dist'n (%)
Main Skarn					
Final Scheelite Con	4.37	0.01	0.29	65.19	94.54
Scheelite Heated 3rd Scav Tail	95.63	0.12	99.71	0.17	5.46
Scheelite Heated Rougher Float Feed	100.00	0.12	100.00	3.01	100.00
No. 2 Skarn					
Final Scheelite Con	8.36	0.01	0.48	67.76	95.01
Scheelite Heated 3rd Scav Tail	91.64	0.15	99.52	0.33	4.99
Scheelite Heated Rougher Float Feed	100.00	0.14	100.00	5.96	100.00

Following the scheelite rougher stage, the concentrates produced from the Main and #2 Skarns were combined to produce a final concentrate to enable testwork for the production of Ammonium Paratungstate (APT) to be conducted at Central South University in Changsha.



The reagent regime and indication of dosage rates as determined in the testwork will be summarised in a flowchart that can be found towards the end of this section.

3.3.5 Gravity Testwork

GZRINM also manufacture gravity separation equipment. The plan was for GZRINM to classify the calcite flotation tails at ~26µm. The finer (overflow) fraction was kept for the fine or secondary calcite flotation tests. The coarser (underflow) fraction was then subjected to a spiral separation via a GZRINM manufactured spiral. Approximately 75% of the mass reported to the classifier underflow stream for spiral testwork.

The spiral was of the same diameter, 600 mm, as the CPG Mineral Technologies FM-1 spiral but could generate four products (three stream splitters) as opposed to three products (two stream splitters). The spiral also had only 5 turns as opposed to 6.5 turns. At the completion of the spiral testwork, the spiral tail was to be ground in a ball mill to a P80 of ~40µm and then combined with the initial overflow fraction to complete the feed stream for secondary calcite flotation testwork. The final spiral concentrate and middlings streams were dispatched back to CPG Mineral Technologies to complete the gravity testwork program. All spiral streams were maintained as separate skarn samples.

During the spiral testwork it was decided to re-pass the two middlings streams generated from the first pass back over the spiral to minimise the effect of the different cutting arrangement and to produce a result that more likely represented what would be achieved from a FM-1 model. This is depicted in the following diagram.

From the above diagram, the concentrate from the first pass was designated as the concentrate stream collected for testwork for CPG. From the re-spiralling of the two middling streams, the concentrate and the stream from the inside middlings cutter generated the middlings stream that was collected also for further testing by CPG. The second middlings stream and the second spiral tail were combined with the tail from the first pass to become the primary gravity tail. This combined stream was then reground in a ball mill to the required grind size and then combined with the initial classifier overflow to enable the secondary (fine) calcite flotation testwork to be performed.

The results of the samples sent back to CPG are included in the following tables. It is noted that a very high recovery of cassiterite to the gravity concentrate stream is evident from this testwork.

Main Skarn:

Product	Wt.%		Assay,%		Recovery,WO_3%		Recovery,Sn%	
	Stage	Rom	WO_3	Sn	Stage	Rom	Stage	Rom
Conc 1	8.89	6.15	0.160	4.00	46.55	4.54	64.88	52.43
Conc 2	7.42	3.95	0.034	1.06	14.00	0.63	35.14	9.18
Mid1.2	35.14	18.73	0.016	0.22	31.40	1.39	34.54	9.01
Feed		28.83	0.049	1.14		6.56		70.62

#2 Skarn:

Product	Wt.%		Assay,%		Recovery,%	
	Stage	Rom	WO_3	Sn	WO_3	Sn
Conc 1	6.18	4.10	0.18	2.90	1.43	47.86
Conc 2	29.29	16.93	0.04	0.65	1.26	22.75
Mid 1,2	30.26	17.49	0.014	0.15	0.44	5.42
Feed		38.52	0.043	0.66	3.13	76.03

The following table includes the spiral test results of the stream designated as “gravity tail” which was then reground in a ball mill and also the initial coarse classification overflow. These streams were combined to conduct the fine secondary calcite flotation testwork. The results are as follows:

Main Skarn:

Product	Wt.%		Assay,%		Recovery,%	
	Stage	Rom	WO_3	Sn	WO_3	Sn
Spiral Tail1	14.15	9.80	0.017	0.11	0.76	2.30
Spiral Tail2	3.87	2.06	0.019	0.23	0.18	1.04
Mid2.2	53.38	28.54	0.017	0.11	2.25	6.87
Overflow	25.17	23.29	0.034	0.50	3.60	16.80
Feed		63.69	0.023	0.15	6.79	27.01

#2 Skarn:

Product	Wt.%	Assay,%		Recovery,%

3.3.7 Overall Testwork Flowsheets and Summaries

The following flowsheets summarises the overall flowsheet and reagent conditions developed at GZRINM. One conclusion evident from the tests is that due to the high recovery of Scheelite in the initial primary calcite flotation, the secondary flotation step may become redundant due to the small value this step provides in the overall process.

Another point highlighted by these tests is also the excellent cassiterite recovery achieved in the spiral testwork. Overall feed to the tin flotation circuits appears to be low at 0.15% Sn and 0.125% Sn for Main and #2 Skarns respectively.

3.4 Alternative Collector to GYW-A Reagent

It was anticipated that samples of the GYW-A reagent would be made available to continue the testwork program in Perth with the blended skarn samples. However, GZRINM insisted that no additional reagent would be released for testwork until after the GZRINM program was completed in order to protect the institute's intellectual property in terms of reagent development. From the perspective of Venture Minerals, the sensitivity of GZRINM towards their reagent posed a commercial risk to the project. It was discovered that an alternative fatty acid reagent was available, LF-1, which by all accounts produces similar metallurgical results to GYW and GYW-A.

Tony Choo conducted the test work with LF-1 as the scheelite collector reagent in the program conducted at BV Amdel with material from the Blended Skarn composite. The overall results from this work indicated that LF1 can be used successfully in the calcite and scheelite flotation processes. However GYW-A still remains the preferred collector. The LF-1 reagent still delivered comparable results but with marginally less selectivity in comparison to the results achieved with GYW-A.

The results contained in the table below indicated that a final scheelite concentrate grade of 65.5% WO_3 was achieved.

3.5 Gravity Testwork Conducted at CPG Mineral Technologies

3.5.1 Background

Testwork to delineate a gravity circuit flowsheet for concentration of "coarse" cassiterite was undertaken at the laboratory of CPG Mineral Technologies (MT) in Carrara, Queensland on two sets of samples.

The first set of samples were generated from an FM-1 Spiral Separator rougher stage on material produced from the "50:50" blended composite of the two skarn ores. Samples of Feed, Concentrate and Middling fractions produced from testwork conducted by Bureau Veritas – Amdel in Perth were sent to MT. The feed stream for this work and also that for the coarse classification cyclone ahead of the FM-1 spiral was the calcite rougher flotation tail produced using the alternative reagent to GYW-A, that is LF-1.

The second series of testwork was conducted on samples produced from separate processing of the two skarns at GZRINM. The samples tested were "Coarse" Primary Calcite Flotation Tailings streams which were deslimed at nominally 30µm then subjected to gravity separation in China using the GZRINM 5-turn spiral separators. The spiral test fractions were dewatered and shipped to MT in Queensland for further gravity testwork.

Several options had been previously considered. Upfront gravity separation was considered but eliminated from the proposed flowsheet in favour of grinding all feed material to P_{80} 125µm to liberate most of the iron and sulphide minerals and allow their recovery/removal via magnetic separation and sulphide flotation. Consideration was also given to incorporating a stage of high intensity magnetic separation to remove paramagnetic minerals identified in the ore, but this option was subsequently eliminated from the proposed flowsheet due to uncertainty about the amount of this material across the ore.

The aim of the proposed testwork by MT was to better define the gravity separation stages in the flowsheet, processing deslimed, non-magnetic, sulphide and "coarse" primary calcite flotation sinks material, and determining what tin grade can be achieved in the gravity concentrate.

Further upgrading of the gravity concentrate is likely to include sulphide and scheelite flotation to remove additional residual material that will have concentrated with the cassiterite. The gravity tailings will require regrinding to P_{80} 40-45µm for subsequent desliming and cassiterite flotation. The gravity and cassiterite flotation concentrates will be blended together to produce the final tin concentrate for sale to smelters.

3.5.2 Gravity Testwork on Blended Skarn Sample

Three samples of blended Mt Lindsay ore were received from Amdel (Perth) for gravity circuit testwork. The samples were prepared spiral feed, spiral concentrate and spiral middling. The feed sample was characterised in terms of assay by size analysis and spiral release testwork was conducted on an FM-1 model spiral separator to compare the performance with the results achieved by Amdel using the same spiral model.

The spiral concentrate and middling samples (produced by Amdel) were each subjected to additional FM-1 spiral release testwork to constitute cleaner and scavenger stages. Reserve samples from the spiral testwork were processed over stages of wet table separation to evaluate performance and determine the potential for producing high grade tin concentrate.

- **Rougher Spiral Feed**

  The feed sample contained 0.44% total Sn and 0.09% WO_3 as the valuable components. The sample also contained 0.15% As, 0.54% S and 19.7% Fe. Soluble Sn comprised approximately 10% of the total Sn value. B and F levels were determined to be 0.14% and 0.62% respectively.

  The sample had been milled to an advised target P_{80} of 125µm and deslimed. The particle size range of the sample was ideal for the FM-1 spiral with a D50 in the order of 90µm and minimal mass below 20µm. 80% of the Sn and 90% of the WO_3 were coarser than 45µm.

  Rougher spiral release testwork confirmed good upgrading of Sn and WO_3 with grades of approximately 5% Sn and 1% WO_3 achieved in a low mass yield of 6% at recoveries of 60% and 70% respectively. Testing at two different feed rates indicated that higher feed rates of up to 1.5t/h could be used with only a small decrease in performance compared with a standard feed rate of 1.0t/h. Feed slurry density was maintained at approximately 35% solids.

- **Rougher Spiral Middling**

  The received sample contained 0.2% total Sn and 0.013% WO_3. The sample also contained 0.13% As, 0.4% S and 19% Fe. Soluble Sn comprised approximately 10% of the total Sn value. Soluble Sn, B and F levels were determined to be 0.05%, 0.13% and 0.46% respectively.

  Spiral release testwork indicated the feed contained residual gravity recoverable Sn and WO_3 with grades of approximately 0.9% Sn and 0.05% WO_3 achieved in a low mass yield of 5% at recoveries of approximately 20% for both Sn and WO_3. A single feed rate of 1.0t/h at 35% solids density was tested but based on the rougher stage results it is expected that a higher feed rate could be used with minimal decrease in performance.

- **Rougher Spiral Concentrate**

  The received sample contained 1.6% total Sn and 0.27% WO_3. The sample also contained 0.5% As, 1.2% S and 23% Fe. Soluble Sn comprised approximately 10% of the total Sn value. Soluble Sn, B and F levels were determined to be 0.06%, 0.25% and 0.48% respectively.

  Spiral release testwork indicated good upgrades of Sn and WO_3 with grades of approximately 8% Sn and 1.5% WO_3 achievable in a mass yield of 12% at recoveries of 70% and 80% respectively. A single

feed rate of 0.9t/h at 24% solids density was tested but based on the rougher stage results it is expected that a higher feed rate could be used with minimal decrease in performance. The low feed density was due to the small mass of feed available. The typical feed density would be 30 to 35% solids.

Reconstituted samples from the spiral release testwork were processed over a two stage wet table circuit with the second (cleaner) stage treating concentrate from the first (rougher) stage. From the second stage a concentrate was produced at a table circuit mass yield of 0.9% that contained 52.9% total Sn and 9.8% WO_3. The concentrate also contained relatively high levels of As (5.9%) and S (1.3%). Recoveries of Sn and WO_3 in the wet table circuit were 29% and 32% respectively. The relatively low recoveries were due to the requirement for producing a Sn concentrate of the highest possible grade. A concentrate of lower grade containing 18% total Sn, 3% WO_3, 5.7% As and 3.4% S could be produced (in a table circuit mass yield of 7.5%) at recoveries of 80% (Sn) and 86% (WO_3) respectively and should be suitable for feed to a flotation circuit to remove sulphides (As and S).

Based on results provided by Amdel for the rougher stage bulk spiral processing which produced the concentrate for table testwork conducted by MT, the overall recovery of Sn and WO_3 was 15% and 22% respectively (calculated back to prepared rougher spiral feed) to produce a high grade Sn concentrate at an overall mass yield of 0.10%. The lower grade concentrate (18% Sn) achieved recoveries of 42% (Sn) and 57% (WO_3) at an overall mass yield of 0.85%.

3.5.3 Gravity Testwork on Main Skarn and #2 Skarn Samples

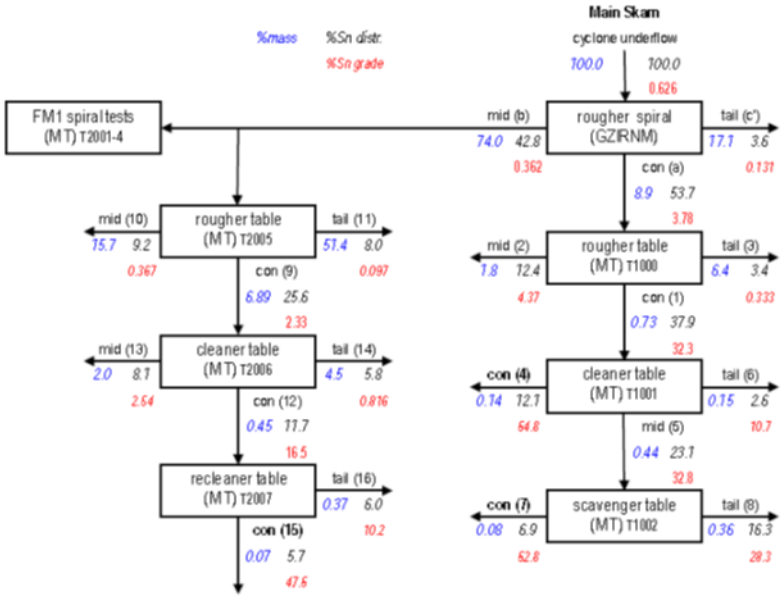
Due to the low mass of the concentrate samples (one from each skarn ore), the fractions were individually separated using a wet shaking table circuit to recover a high grade cassiterite concentrate, with sub-samples of table products being extracted for assays. The plan was to then proportionally recombine the remaining samples to form a single concentrate sample for FM-1 spiral release testwork, but this plan was abandoned due to lack of material after consultation with Venture Minerals.

The spiral middling samples (two from each skarn ore) were combined to form a single middling sample for each skarn. With the larger mass available, these samples were processed with an FM-1 spiral (release testwork only) and then the remaining / reserve material was separated using a wet shaking table circuit to recover cassiterite.

Spiral testwork was conducted in a closed circuit test rig consisting of the test spiral separator (single start), sump and pump and full-stream deflection samplers. The pump discharge went to a distributor with a portion of the feed stream reporting to the spiral feed box and the remainder returning to the feed sump. The concentrate splitters are adjusted to recover the high density material to a concentrate channel, whilst intermediate density and low-density streams are directed by further splitters into individual product collection channels within the product collection box. Each stream then returns to the pump sump via timed, full-stream deflection samplers.

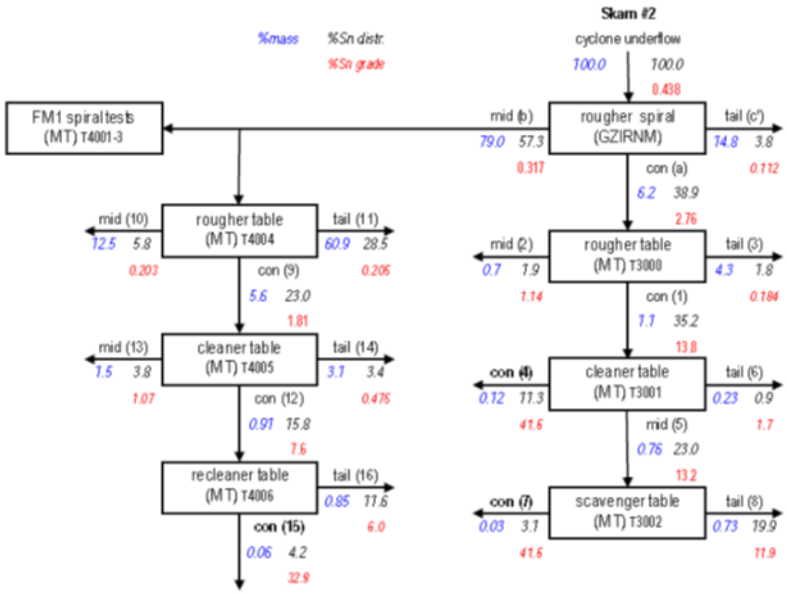
The test rig is started up with water and solids added to the sump until the required test parameters were established. For testing of fine feeds, the homogeneous feed was held at the desired pulp density as slurry in an external tank and was transferred to the spiral feed sump as required. The samplers were then operated and the products collected separately. The products were weighed wet and then dried. The resultant data were then processed and used to calculate the physical parameters (mass flowrate (t/h) and % solids) of each stream and the feed. Sub-samples of each stream were then representatively extracted, using riffle or carousel splitters, for assay purposes.

For wet shaking table testwork *Holman 2000* (one-quarter of full size) and laboratory-scale *Wilfley* models were employed for the duty. The general testwork procedure is as follows:



- Dry or dewatered feed was introduced at a constant rate into the feed box and dilution water was added.
- The products were collected into buckets with the aid of manually positioned splitters.
- Products were then dewatered and dried.

- The dried products were weighed and a sub-sample representatively extracted from each using a riffle splitter for assay purposes.



The *Wilfley* laboratory-scale table was used as an analytical tool and not used for process design testwork. Process design testwork would be based on scaled up data from *Holman* table testwork. To test a possible table circuit, bulk wet table processing was conducted using a circuit comprising of a feed sump and pump with pump discharge reporting to a distributor with a portion of the feed stream reporting to the wet table feed box and the remains returning to the feed sump. New feed was added to the feed sump at an equivalent rate in order to maintain constant operating conditions.

Results from tabling test work are summarised, with respect to mass and Sn distribution and Sn grade, in the flow diagrams below:

MAIN SKARN

#2 SKARN

3.5.4 Overall Results and Proposed Gravity Circuit

Overall gravity circuit results were also combined to illustrate cumulative mass and elemental balances relative to the GZRINM Rougher Spiral Feed (for Sn & WO_3) and/or Con+Mid (for all other elements) and a combination of the three highest grade product streams resulted in the following combined concentrate grades and recoveries:

Ore	Main Skarn			#2 Skarn		
Element	Grade	Recovery		Grade	Recovery	
		(to RS F)	(to RS C+M)		(to RS F)	(to RS C+M)
Sn	52.4	24.6	25.6	39.2	18.7	19.4
WO_3	1.93	25.4	29.3	0.75	4.7	5.2
As	2.61	-	23.6	5.47	-	7.8
Fe	8.32	-	0.1	18.7	-	0.2
S	0.23	-	0.3	2.81	-	0.7
Sol. Sn	0.041	-	0.2	0.009	-	0.1
B	0.088	-	0.2	0.017	-	0.4

For both the Main Skarn and #2 Skarn samples, as recovery of tin to gravity concentrate increased (i.e. including more table streams in the final concentrate), the concentrate Sn, WO_3 and As grades decreased and the Fe, S and B grades increased significantly, due to lower specific gravity (than cassiterite, scheelite and arsenide minerals) iron and sulphide and vonsenite minerals being included in the concentrate.

Some fine mineral (FM-1) spiral separation testwork was also conducted on the larger (combination of two) Chinese Rougher Spiral Middlings stream for comparison and results showed that further recovery of liberated tin minerals was possible. Overall the results showed that:

- High grade tin concentrates were able to be produced using a wet shaking table.

  Main Skarn – concentrate grade >50% Sn
  #2 Skarn – concentrate grade ~40% Sn

- The main contaminants in the gravity concentrate and middlings streams are Fe, As and S.
- The grades of these contaminants are all generally higher for the #2 Skarn sample products compared to those from the Main Skarn sample.
- As may be present in the form of arsenide and/or arsenopyrite.
- Removal of sulphide minerals, such as arsenopyrite, and also scheelite from gravity concentrates may be possible using flotation.

Overall the testwork indicated that a flowsheet is likely to include at least two full stages of spiral separation (likely to be rougher and mids scavenger) followed by three stages of tabling (likely to be rougher, mids scavenger and cleaner).

Subsequent tests should use the largest wet shaking table possible (based on available mass) for each stage to provide a better indication of likely performance at full-scale. The reprocessing of selected middlings / tailings streams to enable better process control of overall tin grade and recovery from the gravity circuit. As there also exists near density minerals to cassiterite such as arsenopyrite and scheelite, then further improvements in final grade can be expected through incorporating sulphide and scheelite flotation on the gravity concentrates.

The flowsheet recommended from the testwork is represented in the following diagram:

A key aspect of the conceptual process flowsheet is the minimisation of recirculating streams in the wet table circuit. This approach is recommended for a number of reasons, including:

- The benefit of recirculating streams is to recover misplaced valuables (as opposed to unliberated / composite minerals)
- Wet tables are relatively high efficiency separators and, by definition, the quantity of misplaced valuables is likely to be quite low
- There is significant potential for recirculated material to build up and not escape the circuit, resulting in overloading and reduced separation efficiency.

Generally, the concept of recirculating table streams to spirals is not recommended for two reasons:

- Tables are a more efficient separator than spirals, so recirculating a mid or tailings stream from tables to spirals is not likely to result in a metallurgical benefit
- Spiral and table circuits are no longer separate circuits, which can be an issue with operation and performance measurement

The tailings from the gravity circuit are not reject streams and will report to a regrind mill, so there are no direct losses from the circuit. The one stream that is likely to be suitable for recirculation is the middling from the cleaner stage table, as the aim of this stage of separation is to produce a relatively high grade concentrate, so some Sn/WO_3 will be sent to middling. Two other table circuit streams are shown reporting to regrind but with an option of recirculating to earlier stages. The preferred option would be to regrind these streams unless further characterisation confirms that these streams contain misplaced material (i.e. valuables that were contained in these streams not due to liberation and/or particle size issues).

3.6 Gravity Concentrate Flotation Testwork

During the concentration process, near density minerals in terms of SG to cassiterite will also concentrate. Cassiterite has an SG of 7.0. Minerals such as scheelite (SG of 6.1) and arsenopyrite (SG of 6.0) will concentrate with cassiterite. Several exploratory tests using the gravity concentrate produced from scoping tests at BV Amdel on the blended sample were used. This was because sample material from the CPG testwork had been consumed in attempting to establish the correct conditions.

This testwork was completed after the development of the acidifying step which removes the effect of residual fatty acid on particles surfaces. The steps involved for concentrate cleaning are therefore an acidic pre-treatment with H_2SO_4 at a pH of 2 and then a sulphide float with PAX and copper sulphate at natural pH followed by a calcite/scheelite float at a pH of 9 with GYW-A and sodium silicate. The results are summarised in the following table. In these results Fe has not been reported but it would be anticipated that the majority of it would

have been associated with the arsenopyrite. Despite this work not being definitive, these tests demonstrated that the bulk of the final cleaning of gravity tin concentrate could be done. Most of the Sn losses would be entrained finer size cassiterite.

3.7 Tin Flotation Testwork

3.7.1 Background

The flotation of tin (cassiterite) is conventionally performed using styrene phosphonic acid (SPA), sulphosuccinamate (CA540) or sulphosuccinamate (A845). None of these collector types are particularly selective toward cassiterite and both iron and silicate minerals are routinely recovered along with cassiterite. This strongly limits the tin grade, and thus the value, of cassiterite flotation concentrates, hence the need for it generally to be blended with a higher grade gravity concentrate for saleability. Generally, the phosphonic acids provide stronger collecting power, that is, they collect cassiterite ore at a faster rate due to faster adsorption on the oxide surface when compared to sulphosuccinimates. However, SPA is a very expensive reagent and is typically 3 to 4 times more expensive than succinimates.

As a result, tin flotation practice generally includes a “desliming” stage through a series of hydrocyclones to reject particles of 6-8µm from the flotation feed. This has the effect of reducing the surface areas of particles which in turn should reduce the consumption of SPA. Also prior to tin flotation the pulp undergoes a conditioning step using sodium silico-flouride (SSF) at an acidic pH which is generally proceeded by scavenging flotation to remove residual sulphide and possibly a scavenging float using GYW-A to remove trace amounts of calcite and scheelite. The actual tin flotation circuit then becomes more conventional and is generally configured in a series of rougher/scavenger cells with the concentrates being upgraded in a series of cleaner/recleaner circuits. Also pH is controlled by sulphuric acid additions to pH 5.0 – 5.5.

3.7.2 “Desliming Hydrocyclone Testwork”

A standard Mozley hydrocyclone test rig was used for the testwork. The tests were conducted with a 2 inch cyclone complete with an 11mm vortex finder and a 3.2mm spigot. This was to target a cut point of 6µm to remove the fine particles before tin flotation.

The following mass split was achieved when operating at these conditions:

PROPORTIONAL SPLITS :

Sample No.	Overflow m3/hr	Underflow m3/hr	Feed m3/hr	Proportion split to O/F	Proportion split to U/F
1	1.608	0.204	1.812	0.887	0.113

MASS AND VOLUME SPLIT SAMPLES :

	Slurry Wt. g	Dry Wt. g	Solids %	Volume Split	Mass Split
O/F	6629	154.9	2.3%	82.7%	16.0%
U/F	1389	814.0	58.6%	17.3%	84.0%
Feed	8018	968.9	12.1%		

3.7.3 Scavenging Flotation, Conditioning and Rougher Flotation Testwork

The flowsheet initially proposed included two flotation steps prior to pulp conditioning. These steps were to remove residual sulphide minerals followed by a step to remove residual calcite/scheelite minerals. The flotation tailings stream would then be conditioned with SSF ahead of tin flotation. This testwork, reported by Tony Choo in July 2012, was occurring in parallel to engineering and it is the case that this and later results have not been transitioned into the engineering study.

The sample used in this study was the deslimed blended sample where the calcite and scheelite flotation circuits were tested using the alternative LF-1 reagent. However, it was found that the use of AP830 could replace LF-1 in the fine secondary calcite flotation in recovering scheelite (and calcite and fluorite by extension) and not have an adverse influence on the froth characteristics in subsequent tin flotation. The use of AP830 does not necessitate the addition of soda ash or sodium silicate and as a collector commonly used in the flotation of sulphide minerals, also collects sulphides at the same time as recovering the calcite/scheelite. The result of this meant that the scavenging flotation can be undertaken in a single stage. Another part of the justification is that the feed to the tin flotation circuit in generally too low in calcite/scheelite to justify its own scavenging circuit separate to sulphide minerals. This finding is similar to the conclusion from the fine calcite/scheelite flotation tests conducted at GZRINM.

Scoping tests were completed to improve on froth selectivity and cassiterite recovery. A pre-treatment step was required and this entailed the use of sodium silico-fluoride (SSF) to be added and adjusted with H2SO4 to pH 2 and then attrition for 15 minutes before desliming with a cyclone. This was to clean the surfaces to improve the surface chemistry and to eliminate the effects of the fatty acid collector from the scheelite floats.

The scavenging tests were undertaken at a pH of 8.5 – 8.6 which is the resultant pH of the calcite flotation tailings stream from the primary or coarse calcite flotation circuit. AP830 was added at the rate of 270 g/t with 150 g/t initially added and two subsequent additions of 60 g/t after 3 minutes each. Following this the scavenger tail was then conditioned with 490 g/t SSF for 15 minutes. pH control was also maintained with sulphuric acid. From here through to the flotation roughing circuit, pH is controlled within the range of pH 5.0 to 5.6 and 1500 g/t of H2SO4 was consumed. Three rougher concentrates were collected after every 10 minutes. Recovery of cassiterite was good, despite the slow flotation kinetics, and that the majority of the tin losses is actually associated with Vonsenite which is measured by the soluble tin (AR Sn) assays.

The following table summarises the above testwork:

Test 128: Collector AP830 150, 60, 60 Dep C: 0 IF6500: 60, 12, 13
Collector SPA/Tall Bennet 340, 110, 110 H2SO4: 1500 SSF: 490 IF6500: 0, 0, 8

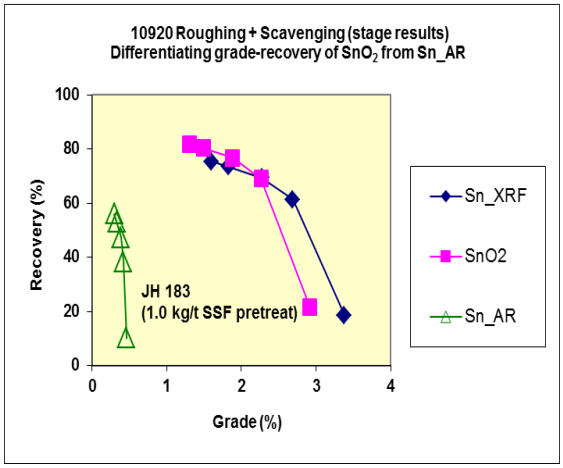
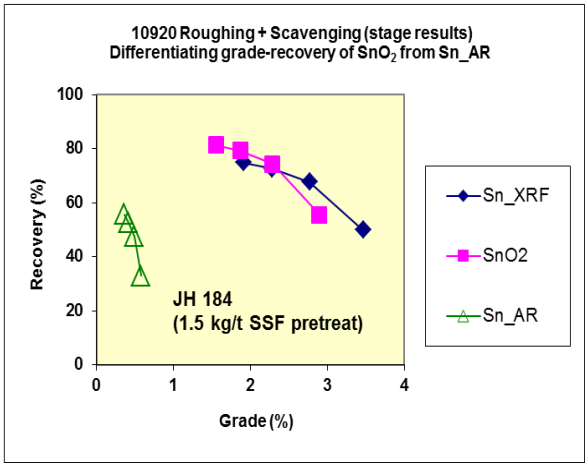
3.8 Further Developments

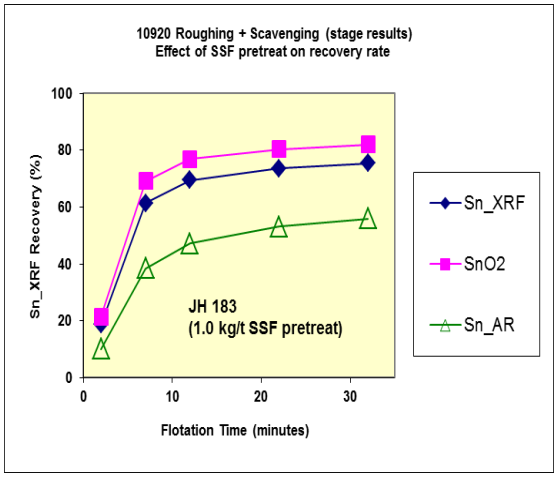
From the above results, consideration was given for ways to improve the flotation kinetics of cassiterite. Attention turned to “acidified sodium silicate” (ASS) which was used successfully in conjunction with tin flotation collector CA540 at the Wheal Jane operation in Cornwall, UK. It was also trialled in production at the Renison plant in 1995-1996. Whilst the trial did not result in a change to ASS for Renison, it was considered that there is potential in bettering the SSF regime for Mt. Lindsay ore. In short, the conclusions from this work indicated that the resultant froth conditions were not encouraging and resulted in poor rougher concentrate grade and recovery.

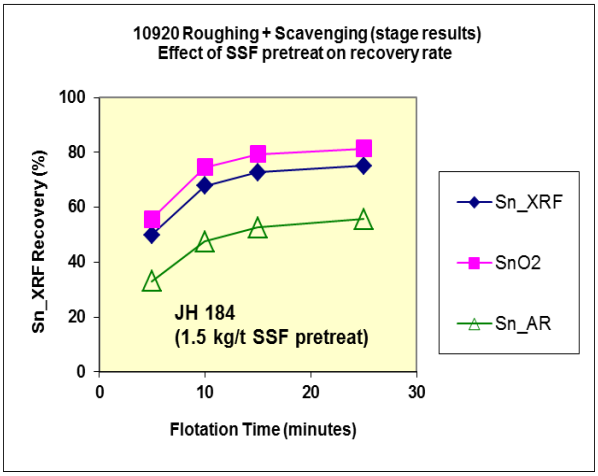


As an alternative to the above, an acidic SSF pretreatment (SSFPT) step was investigated. SSFPT involves the use of sulphuric acid (at pH 2) and SSF in conditioning feed slurry under agitation. It is proposed that the feed has already been deslimed at ~6-8µm by hydrocycloning. After the agitation time has been reached, the slurry is then deslimed again. Cyclone overflow is then rejected as per normal slime tail. Up to 1500 g/t of SSF was used in the scoping tests. Because the bulk of the calcite inherent in the run-of-mine ore has been recovered by the primary calcite floats the use of acid was not expected to be problematic. The relatively large SSF dosage is normally detrimental to tin flotation, but in this case most of it would be removed to the cyclone overflow fraction and therefore leaving only an "optional" booster dose in SSF during the tin flotation process to sustain selectivity.



The hypothesis in using SSFPT is that the synergy of acid and SSF plus interparticle collision under agitation would cleanse and "refresh" mineral particle surfaces for more efficient interaction of any intended conditioners, depressant(s) and collector by removing prior-adsorbed fatty acids, surfactants and slimes coating from grain surfaces. In addition SSF exhibits some beneficial buffering effect in stabilizing pH during flotation. This would mean that subsequent consumption of acid would be minimal. The results achieved in JH182-186 substantiated the hypothesis and once again SPA outshone the other collectors as the one most amenable to SSFPT application (see the graphs below).





Another beneficial aspect of SSFPT is the apparent reduction in SPA demand for flotation. The relative cost ratio of SPA to SSF is about 12 to 1. The next set of charts focus on the results of cassiterite tin (SnO_2) from SSFPT and differentiates it from total tin (Sn_XRF), which also consists of the acid-soluble tin (Sn_AR) component. The SnO_2 assay is calculated by the difference between Sn_XRF and Sn_AR assays. The Sn_AR component mainly in the form of Vonsenite is significantly less recoverable to grade than cassiterite, therefore while its recovery incrementally adds on to the total tin metal units it disproportionately drags down the overall tin grade, negatively impacts on recovery kinetics which masks the actual flotation performance of cassiterite tin.

An improvement in flotation kinetics by increasing SSF addition from 1.0 kg/t to 1.5 kg/t was also achieved. This can be seen in the following charts that upon removing %Sn_AR assay from %Sn_XRF the tin flotation results are encouraging. Similarly, SPA (and other tin oxide collectors) also floated scheelite but there were only traces of WO_3 remaining in the tin flotation feed, due to the high recovery from the GZRINM process. This is likely to make obsolete the use of a dedicated calcite pre-float in scavenging scheelite from tin float feed. Given that % CaO in the feed was acceptably low, no calcite pre-float was performed which is different to the current process design. A residual sulphide flotation step still exists as part of the pre-float process ahead of tin flotation.

Due to the number of scoping tests required to determine initial operating conditions, there was not sufficient rougher concentrate generated to undertake additional cleaning and recleaning flotation tests. Tin flotation with SPA collectors is an industry standard practice for recovering fine cassiterite.

Due to the incorporation of the SSFPT process, the testwork completed produced a relatively good rougher concentrate grade of ~3% Sn from a feed grade of 0.3% Sn at an acceptable recovery. This gives confidence that an acceptable flotation final tin concentrate can be produced in 3 to 4 stages of cleaning/recleaning.

Phase 1 Testwork

Phase 2 Testwork

Mount Lindsay Metallurgical Testing

INTRODUCTION

The Mt. Lindsay project intends to generate magnetite, chalcopyrite, cassiterite and scheelite products for sale. Scheelite can also be manufactured into ammonium paratungstate (APT). Testwork is required to be completed at a sufficiently high standard for evaluation of a number of processing options in order to delineate a relatively extensive flowsheet.

Scoping Studies

Several initial conceptual/scoping development studies have been carried out since 2008 by a number of consultants. The initial mineral processing test programs utilised methods that would be considered standard and results were based on assays and mineralogical analysis. The early programs encompassed:

- mineralogical and liberation studies, particularly to determine the appropriate primary grind size of the ore;
- magnetic separation especially for separation of magnetite from the ore;
- flotation, especially cassiterite and scheelite flotation, but also sulphide flotation which was recently extended to include differential flotation of chalcopyrite; and
- gravity separation.

The initial scoping study concluded that the Mt. Lindsay project has the potential to become a profitable operation with the primary drivers being the relatively high prices for tin and tungsten, which reduces the impact caused by the appreciated exchange rate. There is also the additional benefit of some of the operating costs being offset by production of a saleable magnetite concentrate into a buoyant iron ore market.

Prefeasibility Study (PFS)

The PFS report was finalised in May 2011. General feedback is that a study more akin to an advanced scoping study has been completed. This is not a criticism but more reflects the complex flowsheet that is required to be developed. However the PFS did achieve a confirmation of the technical viability of the processes nominated and did conclude with a broad flowsheet; albeit not balanced and not with the various circuits fully configured. This flowsheet is contained within the PFS document.

Agreement on the basic parameters for the grinding, magnetite concentration and sulphide flotation circuits was achieved. After two-stage crushing, the main plant configuration is for a primary grind using an open-circuited rod mill and a ball mill in closed-circuit with Derrick

type screens that target a p80 grinding size of ~120 microns. The classified product is then subjected to a low intensity magnetic separation (LIMS) stage prior to the sulphide flotation circuit. The advantage here is that the tonnage flow delivered to the flotation circuit is lower due to the removal of the magnetic fraction by the LIMS. This magnetic fraction will contain monoclinic pyrrhotite which is also ferromagnetic and exhibits a slower flotation kinetic response than most of the other sulphide minerals. The removal of this mineral will provide benefits to the flotation process including the opportunity to improve recovery of arsenopyrite to the sulphide flotation concentrate. Sulphide rougher tail (SRT) is the feed stream for the scheelite and cassiterite concentration process.

BANKABLE FEASIBILITY STUDY (BFS)

BFS Scope Definition

A BFS focuses on the preferred options arising from the PFS. This is achieved by developing and refining the technical and economic estimates by delineating a final process flowsheet with engineering design and costs in sufficient detail to meet financing requirements. To convert the PFS into a BFS, a significant amount of metallurgical testwork is still required.

Generally the outcomes required to be achieved from a BFS have been listed below:

- Optimise process route and finalise reagent types and addition rates. Assess the treatment schedule to ensure that variations in ore feed are acceptable.
- Identify the effect of minor penalty elements on revenue and product quality/saleability. Resolve any problems with customers and obtain quotes or preferably binding letters of intent or sales contracts.
- Final test work preferably on bulk samples and incorporate results into final plant design.
- Finalise process route selection for detailed analysis and incorporation into the project financial model and schedule. Address issues of product/method licences and negotiate fees. This will be required with the Guangzhou Research Institute of Non-Ferrous Metallurgy (GZRINM) for calcite and scheelite flotation.
- Process route frozen and flowsheets developed in detail including mass and water balances.
- Key plant parameters and equipment specifications finalised. The preferred equipment suppliers have been identified from technical specifications and quotes. The equipment delivery schedule is also determined to highlight long lead time equipment.
- Detailed plant layouts with building designs and tailings/waste disposal layouts. Piping and instrumentation diagrams (P & IDs) for bulk materials take-offs such as civil/structural materials.
- Scaled drawings of major components. Detailed drawings where necessary to enable costs to be determined. Detailed construction plan and schedule.
- Estimates to +/- 15% with 95% probability.

- Estimate costs of construction, details of labour, consumables etc. Assess import costs, taxes and freight if applicable.

The testwork "gaps" in the PFS that require quantifying and evaluating in the BFS centre round the fact that:

- a total mass or water balance and hence indication of product recovery arising from the balance has not been produced.
- only indications or best estimates of recovery have been provided but not necessarily reconciled back to head grade.
- there has been a disconnect between the magnetic and non-magnetic testwork with different grinds being used for the two strands of work. This should be resolved for the next program to ensure that the planned design conditions are followed.
- none of the major circuits have been closed out or configured to the final product stage. Middling type streams need to be fully understood to determine where they re-enter back into the flowsheet.
- no final products have been produced to date for evaluation by smelters and other parties to commence drafting terms for off-take agreements.

BFS Metallurgical Testwork

To facilitate and progress the BFS, a detailed metallurgical testwork program has been proposed and is divided into two phases:

- Phase 1 – for unit processes leading to production of "SRT" known as sulphide rougher tail. This essentially covers crushing, grinding, classification, magnetic separation and sulphide flotation. This phase will also include testwork for production of a magnetite concentrate, chalcopyrite concentrate and a sulphide reject stream.
- Phase 2 – for testwork to configure the flowsheet leading to production of cassiterite concentrates and scheelite either as a concentrate and/or APT. The processes under consideration are a proprietary calcite and scheelite flotation process developed by GZRINM, an APT plant, gravity concentration and flotation of cassiterite and possibly a combined cassiterite scheelite gravity concentrate as an alternative to the PFS flowsheet. Provision has also been allowed for a gravity regrind step too. A tailings stream which will be comprised of final gravity and flotation tails will also be generated.

This approach provides the opportunity to reconcile and evaluate all options for cassiterite and scheelite recovery back to a SRT stream that has been prepared under the same conditions and avoids any concern with regard to variability in sample preparation. Unfortunately this also means that the testwork cannot just focus on the cassiterite and scheelite part of the flowsheet. Testwork has to be systematically progressed from crushing and grinding all the way through.

The Phase 1 Metallurgical program has already commenced. The objective is to, through a series of lab or bench scale tests, establish the conditions for primary grinding, rougher magnetic separation and bulk sulphide flotation (no differential flotation of chalcopyrite) to then produce SRT via pilot scale equipment. All products are being collected for subsequent testing. Rougher magnetic concentrates, sulphide rougher concentrates and a bleed stream of flotation feed (rougher non-mags) for chalcopyrite testwork are all being collected for subsequent tests which have been identified as part of the Phase 1 program.

In total, 3 tonnes of material has been prepared for testing and covers the two main ore types and a blend. The samples are to be used for the entire metallurgical program and comprise:

- 900 kg of McDonald Zone (Main Skarn);
- 900 kg of Radford Zone (#2 Skarn)
- 1,200 kg of a 50:50 blend of McDonald and Radford Zone ores.

The McDonald and Radford Zone samples have just completed the pilot stage. The blended sample has just been prepared and is being processed now.

The Phase 2 testwork program is being scoped and testing will commence in late-October with calcite and scheelite scouting flotation trials. There are two processing options being evaluated the "PFS Option" of a Calcite/Scheelite rougher flotation followed by a high-grade scheelite flotation. APT testwork will be completed on both the low and high grade scheelite concentrates. The calcite rougher tails stream will undergo cassiterite gravity concentration, regrind and flotation. The regrind stream will be subjected to a calcite and a cassiterite flotation step.

The second option is a "Combined Cassiterite/Scheelite" concentration process which has the potential to produce a high grade combined cassiterite and scheelite concentrate by conventional gravity for separation by electrostatic separation. Cassiterite is the conductive mineral. The "Blended Skarn" sample is designated for this work. The proposed testwork will confirm if the middlings streams can follow the calcite/scheelite processes as outlined in the paragraph above.

A major challenge for the program is that in terms of final product there will only be very limited quantities available. This is more of an issue for tungsten (WO_3). Combining the two skarns (900 kg each) at say an average assay of 0.30% WO_3 gives ~5.4 kg of WO_3 in the test sample. The APT testwork will also reduce the amount of WO_3 concentrate available for off-take testing. As an estimate, there may only be about 1 to 2kg of HG >65% WO_3 available for this purpose.

BFS Key Metallurgical Issues

Magnetite Concentrate Production

The PFS tests suggested that the separation of magnetite from cassiterite and scheelite is relatively efficient at a primary grind of approximately 80% passing 120 microns with minimal tin and tungsten carry over to the magnetics. It would be expected that some of this carry-over will be recovered from the cleaner section of the magnetite plant. The magnetite should be reground to a nominal size of 80% passing 45 microns. This size is desirable for both chemical reasons in terms of removal of the sulphur to levels <0.10% (<0.2% is maximum tolerance) in the magnetite concentrate and in physical terms for pellet feed balling. If Venture concludes an off-take agreement with Grange Resources for its magnetite production, consistent quality in terms of particle size and chemistry will become more important.

Chalcopyrite and Sulphide Flotation

The chalcopyrite (Cu) and bulk sulphide flotation process needs to be tested to ensure that the correct feed stock can be produced for the cassiterite and scheelite sections of the plant. Copper flotation testwork has been minimal and a concentrate grade of only 10.8% Cu has been reached - well short of a saleable quality. Other plant design issues that need resolving include determining the number of cleaner stages and the benefits of whether to include a regrind step or not.

Calcite and Scheelite Flotation

Successfully separating calcite and scheelite from cassiterite by flotation is a critical part of the plant design. Tests using collector reagent AP830 worked at coarser particle sizes but overall scheelite recovery was poor. The alternative reagent GYW, developed and tested at GZRINM, seemed more successful with a scheelite recovery of greater than 90% achieved. The exact conditions used are not clear and confirmatory testwork is required.

There is some uncertainty about capital and operating cost of the GZRINM flotation process. The concept of producing a combined coarse gravity product of cassiterite and scheelite with subsequent separation by electrostatic means is being proposed as an alternative.

Cassiterite Gravity Concentration and Flotation

Much of the gravity testwork completed in the PFS was performed with narrow particle size ranges on a superpanner. Whilst this may be reasonable, the program now needs to explore the impact of broader particle size ranges likely to be met in a plant situation. Sufficient sample needs to be processed in the correct size ranges to test the rougher gravity section and also to ensure enough concentrate is produced to enable testing on a cleaner gravity section. Fortunately capital costs for gravity equipment such as spirals are relatively cheap and a provision for additional stages can be allowed for in the design and cost estimate.

Only limited cassiterite flotation testwork has been completed to date. Results from the superpanner enable an estimate of flotation concentrate grade and recovery to be derived. For the BFS the difficulty is ensuring that sufficient material will remain to undertake flotation tests and also determine the number of cleaning stages required to produce a concentrate grade sufficient for blending with the final gravity concentrate. The data available at the moment is not sufficient to size plant and equipment for cassiterite flotation.

Given the positive feedback from Renison, an opportunity also exists to contemplate state-of-the-art Falcon Concentrator technology to partially replace a portion of the fine gravity and tin flotation circuits.

Ammonium Paratungstate (APT)

The GZRINM (Petrov-Zhang) scheelite flotation process produces a low grade concentrate which is then used as the feedstock for the high grade flotation process to produce saleable >65% WO_3 concentrate. This concentrate can also be used as feed to an APT plant. From initial discussions at GZRINM in May 2011, an option also exists for low grade concentrate (~30% WO_3) to be used as feedstock for production of APT. As indicated above, the quantity of concentrate available for testing may become an issue and sufficient detail may not be generated to make a "techno-economic" decision concerning the product mix between scheelite concentrate and APT.

Engineering Testwork

To date, only a few samples have been tested to generate engineering data required for the design of the plant to proceed at a high level of confidence. Comminution type tests have been undertaken to generate data such as unconfined compressive strengths (UCS) and Bond crushing and ball mill work indices. But to fully understand ore type variability, significantly more tests may need to be completed.

Moreover, testwork also needs to be conducted to establish thickener settling rates, filtration rates and bin and hopper flow characteristics. The difficulty is that because none of the circuits were fully configured in the PFS this testwork has not been conducted. It is proposed to conduct this testwork from various streams generated from the 1,200 kg 50:50 skarn blend sample.

IsaMill Technology

The IsaMill is an energy efficient, self-classifying, high intensity, industrial scale grinding machine that requires less energy and a smaller footprint than equivalent ball mills. It is now used extensively in base metals and PGM applications and Grange Resources are intending to install these machines for magnetite regrinding at their Southdown, Albany, WA project. Given the tendency of both cassiterite and scheelite to misreport in

hydrocyclone classifiers due to their high specific gravity, testwork is also recommended to be conducted within the proposed gravity regrind application.

BFS Testwork Schedule

A preliminary estimate of testwork completion is listed below. This is for guidance only and is also subject to testwork findings of interconnected activities. Currently the biggest delay is waiting time for receipt of assays and in all situations, an element of risk associated with freighting and delivery of samples.

Phase 1:

Primary Grinding and Classification	October 2011
Rougher LIMS	October 2011
Sulphide Flotation	
Rougher	October 2011
Cleaner	November 2011
Chalcopyrite	February 2012
Magnetite	
Regrind	November 2011
Cleaner LIMS	November 2011
Pyrrhotite Flotation	December 2011
Concentrate Filtration	January 2012

Phase 2:

Calcite and Scheelite Flotation (GZRINM)	February 2012
APT	March 2012
Cassiterite	
Gravity (primary and regrind)	March 2012
Regrind	February 2012
Flotation	April 2012

BFS Testwork Cost Estimate

Review of Potential Crushing and Grinding Options for the VML Mt. Lindsay Project

Prepared For:	Geoff Beros and Jason Amaranti, Venture Minerals Ltd.	**Authors:**	Dr Ted Bearman and Scott Munro

Executive Summary

Bear Rock Solutions (BRS) have been engaged to provide a review of comminution requirements for the Venture Minerals Limited (VML) Mt. Lindsay project.

The scope of the study is to examine at an Order of Magnitude level:

- Sizing of a crushing and grinding circuit to treat 1.3 Mtpa of RoM feed.
- Use of two/three stage crushing plant to generate a -20mm product for subsequent grinding.
- Two stage grinding circuit comprising of a primary rod mill and a secondary ball mill, with the ball mill closed with a Derrick screen. Final grind size is targeted to have a P_{80} of 120µm.

Preliminary Findings

- Variation of Run-of-Mine top size from 600 to 1000mm and at varying levels of fineness – as assumed in this study – mainly impact the selection of the required crushers. The variation in RoM size distribution does not appear to impact throughput or the ability to generate the required product size – providing the correct crushers are selected.
- Two stage crushing can achieve a -20mm mill feed, but to achieve this size reduction, the crushers need to be set at minimum closed side settings and the screening and secondary crushers need to be oversized to deal with the re-circulating load.
- Fluctuations in RoM feed size distribution, feed strength or degradation in crusher performance due to liner wear, could compromise the ability of a two stage crushing plant to meet the throughput required. Throughput bottlenecking could occur if the re-circulating load becomes unmanageable.
- Re-circulating load in the two stage crushing circuit has a size component less than the closed side setting of the secondary crusher. The amount of fines is relatively high and is likely to be detrimental to crusher performance and could increase the likelihood of packing and mechanical failure.
- If two stage crushing is the required option, VML should contact Metso, or the preferred supplier of crushers. As they will need to provide performance guarantees, they should be asked to provide a statement of the practicality of two stage crushing, in terms of feed size, power consumption and re-circulating load.
- Three stage crushing allows the required throughput and product size to be generated, without pushing the crushers and screen towards their performance limits. The circuit is better suited to absorb variations in feed characteristics and changes in circuit performance.
- Using the three stage crushing approach, it is also possible to reduce the grinding mill feed to -15mm.
- To achieve -15mm product from the three stage crushing plant involves the re-circulation of small amounts of material less than the closed side setting of the tertiary crusher. Should there be a build-up in the percentage of minus CSS in the crusher feed there could be impacts on the crusher performance and an increase in packing and mechanical failure.

- Modelling of rod and ball mill performance is restricted to traditional mill sizing approaches, due to more comprehensive comminution tests being impractical at the current level of study. The traditional approaches have been used to estimate the mill sizing and performance, in association with benchmarking against other similar grinding circuits. Such an approach is appropriate for the current level of study.

- Modelling suggests that to achieve the design rate of 200 tph in the grinding circuit and a final grind size of P_{80} = 120 µm, the following is required:

    - Rod Mill: 3.69 x 5.49m, with a motor power of 950kW;

    - Ball Mill: 4.0 x 5.8m with an installed motor power of 1400kW.

- Simulation of the final mill product size distribution shows that the distribution is a close match to the laboratory tests. Given the level of study this is an indicative finding only, but it shows that the comminution circuit does have the potential to deliver the required product.

- Depending on the ore feed characteristics and the crushing plant performance, the rod mill sizing may be conservative.

- The ball mill sizing needs to be considered in light of the rod mill requirements and the performance of the Derrick screens.

- Reducing the grinding mill feed from -20mm to -15mm does not reduce the size of rod and ball mills required. The -15mm feed is finer than the optimal feed size for the rod mill, compromising throughput and size reduction performance. BRS recommends that -20mm is used as the mill feed size.

Commentary

Comminution Plant

Overall the Mt. Lindsay crushing and grinding plant needs to process 1.3 million tonnes per year of Run-of-Mine feed. Venture Minerals Limited (VML) has requested that Bear Rock Solutions (BRS) study the required crushing and grinding flowsheets at an Order of Magnitude level.

In accordance with VML's direction BRS have examined the use of both two and three stage crushing plants, followed by an open circuit rod mill and a subsequent ball mill operating in closed circuit with Derrick screens. Performance of the Derrick screens is outside of the scope of this study.

In general terms and related to the laboratory work undertaken by VML, the crushing plant will need to generate a -20mm feed for the grinding circuit and the overall grind size should have a P_{80} of 120µm.

BRS have used a variety of flowsheet simulation techniques to examine the crushing and grinding elements and these approaches and the findings are covered in the following sections.

Crushing Plant

The crushing plant is to treat 1.3 million tonnes per year of Run-of-Mine feed, whilst operating for 16 hours at a mechanical availability of 95% and a utilization of 95%.

On the basis of operating for 365 days per year and with a design factor of 1.25, the crushing plant needs to treat 310 tph instantaneously and generate a -20mm feed for the grinding circuit.

Preliminary Crusher Simulation

The standard approach taken by BRS in the simulation of crushing plants is to run a series of "sighter" simulations using the Bruno package from Metso.

For this study, the Run-of-Mine (RoM) standard curves from Bruno were used as the feed stock. The curves used were:

- -1000+0mm, Coarse, Medium and Fine
- -800+0mm, Coarse, Medium and Fine.
- -600+0mm, Coarse, Medium and Fine.

The curves are shown in Figure 1.

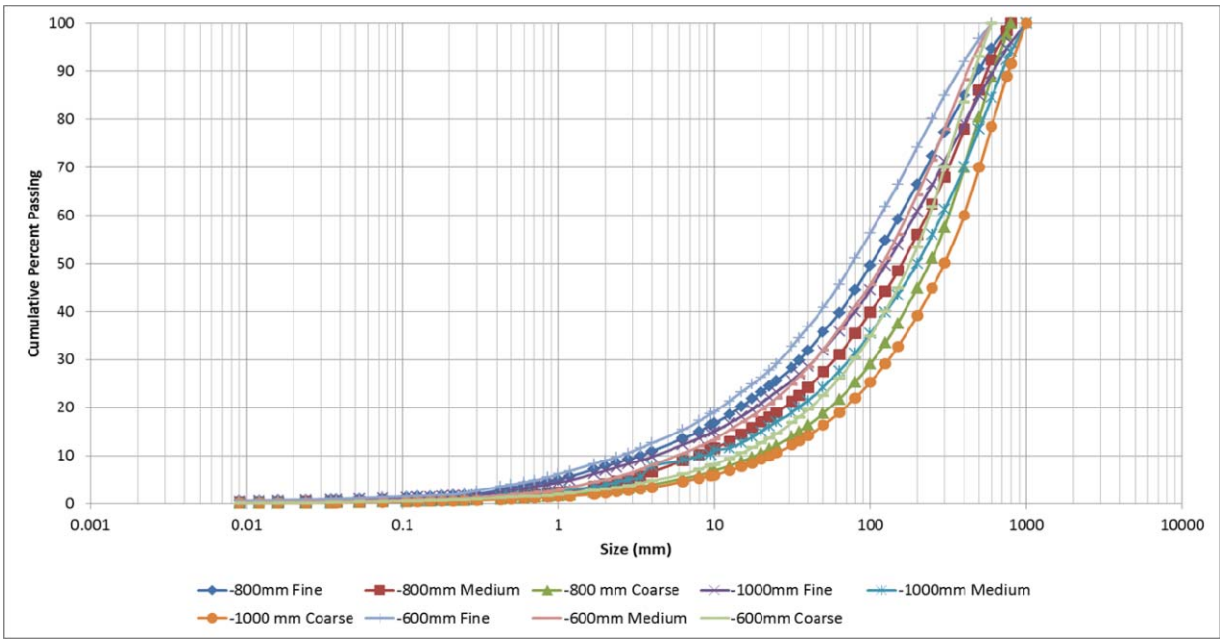

Figure 1: RoM size distributions used as feed stock for the Mt. Lindsay comminution simulations.

The design philosophy used to develop the crushing circuit was to try and minimize the size and number of crushing and screening units, whilst still meeting the required throughput and rod mill feed size of -20mm.

Two Stage Crushing Plant

With two stage crushing, the ability to reach -20mm product is towards the edge of the performance envelope. It will generally require tight (possibly minimum closed side settings) on the crushers and high recirculating loads around the secondary crusher and the closing screen.

The main problem with the two stage design is to find a secondary cone crusher with the right combination of feed opening, minimum CSS, motor power and volumetric throughput. Using the Bruno database, the only cone crusher capable of meeting the requirements is the HP800 Standard with a Coarse liner arrangement.

An HP500 Standard Coarse crusher was considered, but the power required due to the size reduction was in excess of the maximum installed motor power. This assertion is based on results from the Bruno package from Metso and should be confirmed with them or the selected supplier.

The two stage flowsheet with the HP800 is shown in Figure 2.

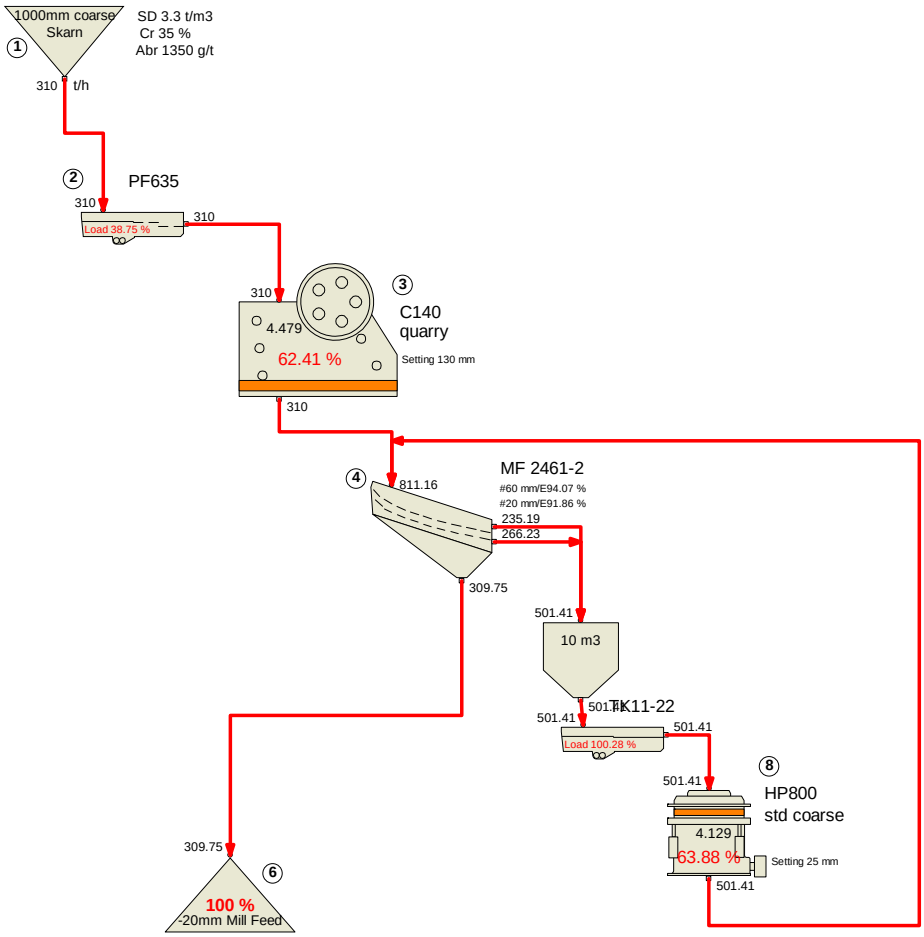

Figure 2: Potential two stage crushing plant with secondary HP800 cone crusher

In regard to the circuit shown in Figure 2, the following should be noted:

- Primary Feeder: Feeder selected in preference to a scalper/feeder, in order to simplify front-end.
- Primary Crusher: C140 with a feed opening of 1400 x 1070mm selected to handle potential RoM feed size distributions.
    - NOTE: With the 1000mm RoM feed curve, there will be some material that may bridge in the jaw opening (normally maximum feed size should be 0.8 x 1070mm = 856mm). Given that VML are targeting an 800mm RoM top size and that the move to a C160 is not desirable (size, cost and minimum CSS), it was decided to stay with the C140. A rockbreaker should be installed at the jaw crusher to manage oversize.
- Screen: A 2.4 x 6.1m banana screen was chosen as there could be significant variations in re-circulating load, particularly as the secondary crusher liners wear.
    - NOTE: Technically the 2.4 x 6.1m screen is oversized, but is included as a risk reduction measure.
- Secondary Crusher: The HP800 Standard Coarse meets the requirements for feed opening, motor power, CSS and throughput.
    - NOTE: The minimum CSS is 25mm and this presents two issues, namely:

        - The difference in screen product cut-size (20mm) compared to the 25mm minimum CSS will develop a re-circulation of the -25+20mm fraction, which will increase as crusher performance degrades with wear.
        - The presence of -25mm material in the cone crusher feed is in excess of manufacturer recommendations for fines content. The presence of such material could cause packing and ring-bounce to occur and the crusher will not be able to achieve the 25mm CSS. Not achieving the design CSS will significantly increase the re-circulating load. In addition, packing in the chamber will increase the probability of mechanical failure.
- Secondary Crusher Feeder: A Metso TK11-22 has been selected, but this has a maximum rating of 500 tph.
    - NOTE: Supplier will need to be contacted to discuss the rating and if needed, alternatives should be considered.

Overall the use of a two stage crushing circuit, whilst possible, is likely to present operational problems that could compromise the ability of the plant to consistently produce at the required rate.

<u>Three Stage Crushing Plant</u>

The move to a three stage crushing plant removes some of the key pressure points identified in the two stage version. The flowsheet arrangement suggested is shown in Figure 3.

In regard to the proposed circuit, the following should be noted:

- Primary Feeder and Jaw Crusher: As per the two stage flowsheet.
- Secondary Crusher Feeder/Scalper: A TK11-42-2V was selected to provide a consistent feed whilst removing -40mm material from the crusher feed, thus reducing the throughput required for the cone crusher and removing material less than the CSS.
- Secondary Crusher: HP300 Standard Extra Coarse.
    - NOTE: The Extra Coarse liner arrangement was selected due to the potential for longer slabs of material from the jaw crusher.
- Tertiary Crusher Feeder: a Metso TK10-15 was selected to provide a consistent, controlled feed to the tertiary crusher.
- Tertiary Crusher: HP400 Shorthead Coarse.
- Screen: A 2.4 x 6.1m banana screen was chosen as there could be variations in re-circulating load due the secondary and tertiary crusher liner wear.

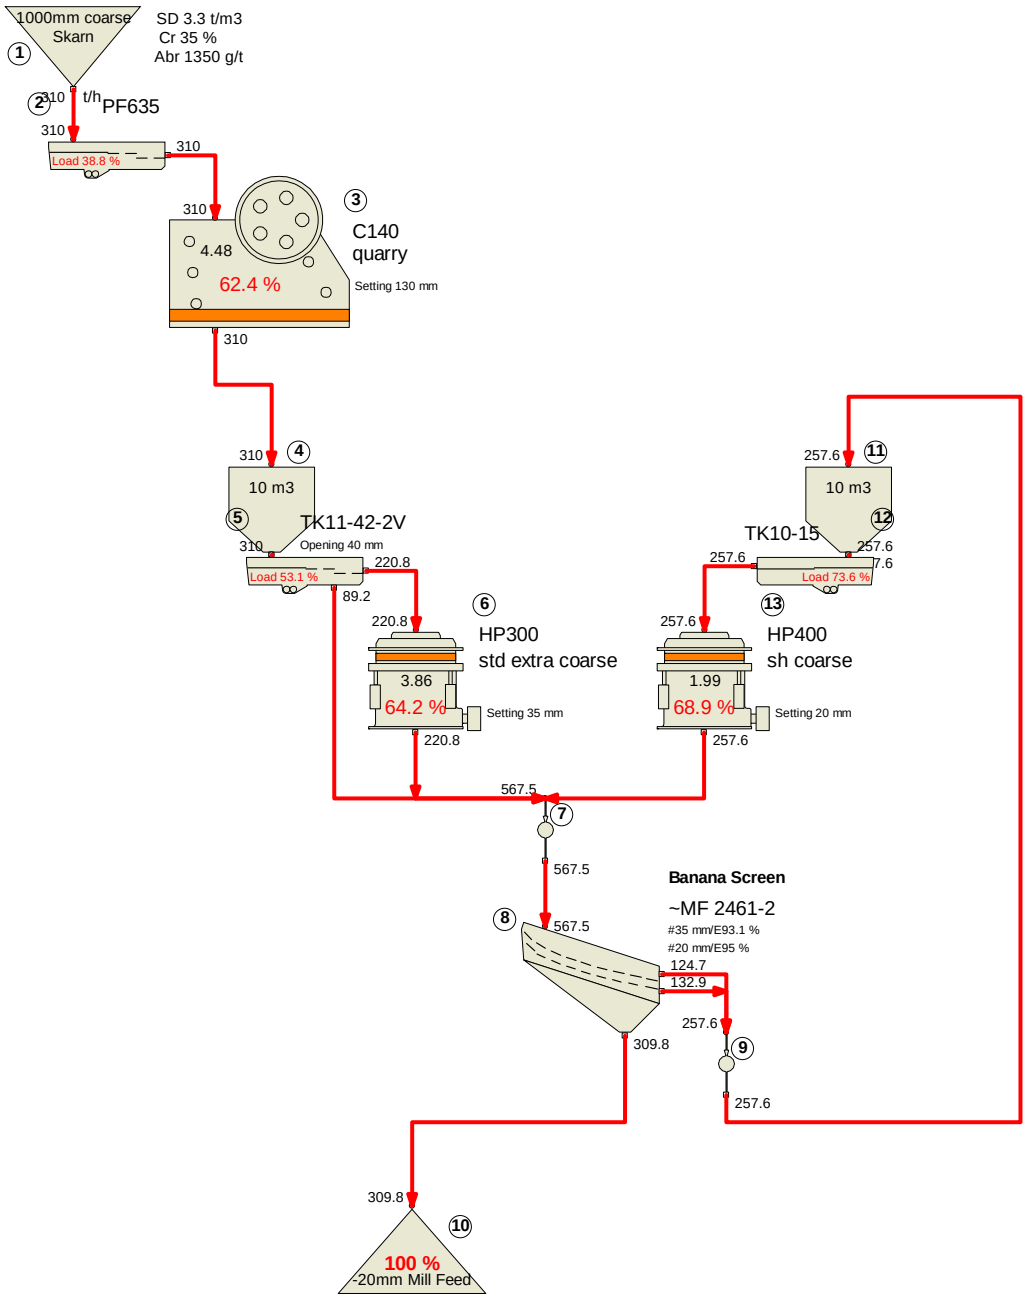

Figure 3: Potential three stage crushing plant flowsheet

With the three stage circuit there is also the possibility to reduce the overall crushing plant product size (rod mill feed) to -15mm. The circuit is shown in Figure 4. The main changes compared to the -20mm product circuit are:

- Tertiary Feeder: Increased in size to the TK11-22 to handle additional recirculating load.
- Tertiary Crusher: Increased from the HP400 to the HP500 Shorthead Coarse and the CSS is reduced down to 15mm.
- Screen: Bottom deck cut-size reduced to 15mm.

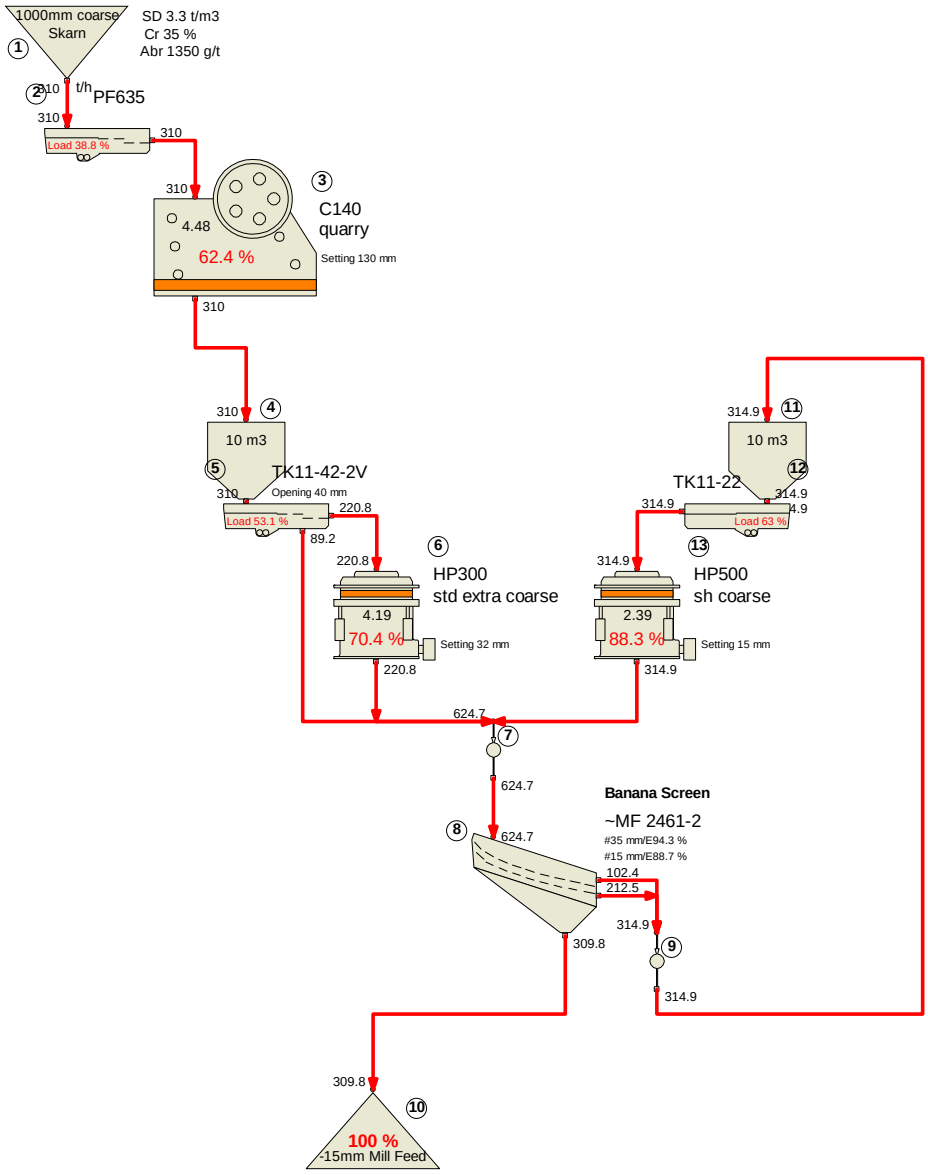

Figure 4: Potential three stage crushing circuit with a -15mm product

With the options having been assessed using Bruno, the potential flowsheets identified in Figures 2, 3 and 4 are believed to be the most realistic flowsheet configurations.

To obtain higher resolution and to tie the crushing plant into the milling circuit, an alternative modelling platform was utilised.

Detailed Crushing Simulation

BRS maintains access to more sophisticated process simulation tools than the Bruno package. The SysCAD flowsheet modelling package has been adapted to include a suite of custom unit operation models including:

- BRS' Kinematic Crusher Model; a mechanistic model of cone and gyratory crushers that can predict throughput, product size and power draw from a crusher's specified liner profiles, feed properties and machine operating settings, without extensive sample data.

- A load-based screening model that determines screening efficiency based on physical parameters such as screen area, panel aperture and shape, screen type (grizzly, banana etc.)
- Jaw crusher, rod and ball mill models based on the JKMRC methodology, adapted for multi-component streams (e.g. Main Skarn/#2 Skarn ore blends).

The two- and three-stage crushing plant flow sheets were simulated in SysCAD using the above models. This provided greater clarity in the expected performance of each unit operation and the mass flows that will result.

Note that the harder #2 Skarn material was used for all simulations, as the crushing and milling equipment must be capable of processing this as a pure feed for extended periods, as per VML direction.

The complete stream details and summary information for each version of the crushing plant can be found in Appendix A.

The main commentary regarding the crushing plant circuit is that:

- The use of “Coarse”, “Medium” or “Fine” RoM curves has no discernible impact on the performance of the plant in terms of throughput and final product size – see Figure 5.

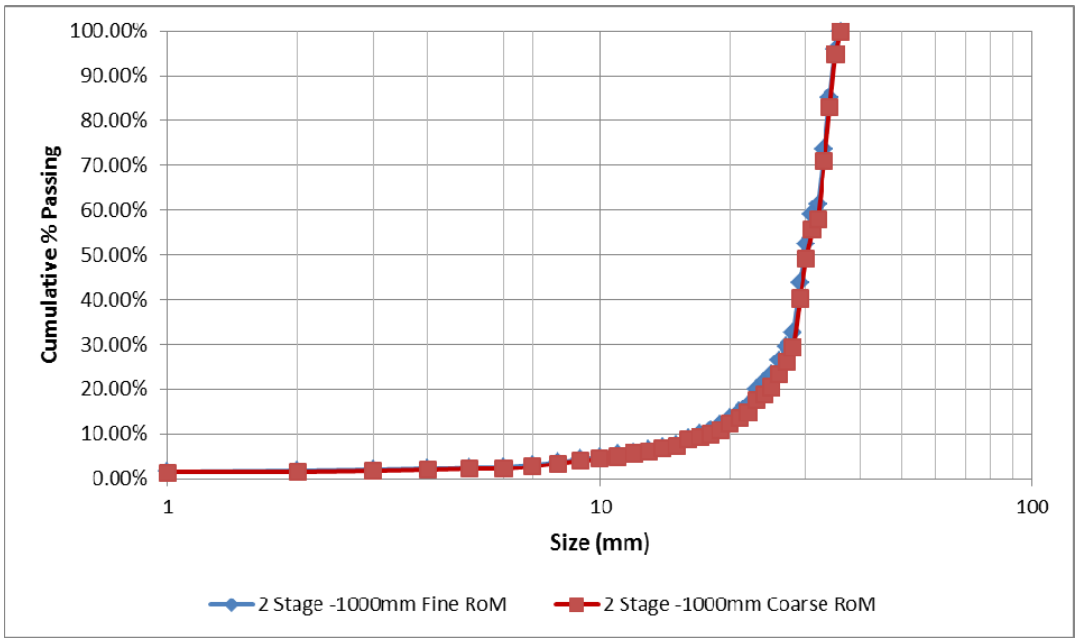

Figure 5: Impact of RoM coarseness on crushing plant product size distribution.

The crushing plant size distributions generated by the two and three stage plants are almost identical for the same target crush size. For the three stage plant there is the option of targeting a -15mm product. The -20mm and -15mm crushing plant product curves are shown in Figure 6.

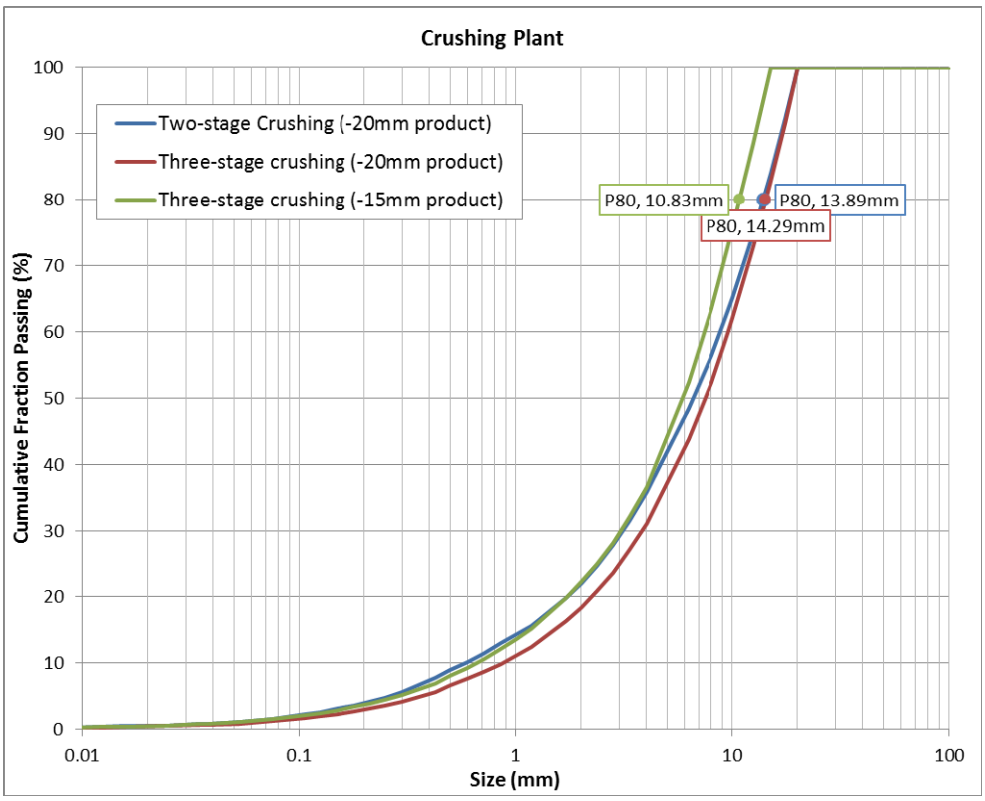

Figure 6: Impact of RoM coarseness on crushing plant product size distribution.

Milling Circuit

On the basis of operating for 365 days per year, with 95% availability, 95% utilization and with a design factor of 1.25, the milling circuit needs to treat 200 tph instantaneously and generate a minus 120µm product.

Grinding Simulation Approach

ALS Ammtec, at VML's request, have undertaken standard Bond crushability, rod and ball mill tests on material identified as 'Main Skarn' and '#2 Skarn'. The results of these tests indicate the #2 Skarn material is somewhat harder than the Main Skarn, as seen in Table 1 below.

Table 1: Summary of VML supplied ore characteristics

Property	Main Skarn	#2 Skarn
Bond Crushability Work Index (kWh/t)	10.6	N/A
Bond Rod Mill Work Index (kWh/t)	15.0	19.0
Bond Ball Mill Work Index (kWh/t)	12.2	14.4

The ore breakage data provided by VML allows for the use of traditional mill sizing, which for this level of study is wholly appropriate. If additional sample material becomes available, VML should consider undertaking further breakage characterization using the drop weight or SMC test. Such additional tests would allow greater resolution in terms of product sizing, but it would probably not impact the mill sizing calculations.

Mill sizing was undertaken by first conducting a survey of both mill vendors and similar rod-ball circuits to identify 'typical' performance parameters that could be reasonably targeted. Table 2 below outlines some of this pertinent survey information.

Table 2: Rod-ball mill benchmarking information

Property	NBHL	Strathcona	ERA	Dome	Thompson Creek
Rod mill					
Throughput (t/h)	115	200	200-220	155	250
F80 (µm)	10,000		12,860		
P80 (µm)	600		2.04		1000
Mill size (diameter x length, m)	2.44 x 3.66	3.2 x 4.9	3.12 x 5.04	3.2 x 4.3	3.7 x 5.8
Motor Size (kW)	375	700	700	525	
Pulp Density (%)		82			79
% Critical Speed				70	
Ball Mill					
Throughput (t/h)	196-428				
F80 (µm)	1000				
P80 (µm)	420	150	270	72	340
Mill size (diameter x length, m)	2.44 x 2.74	4.0 x 7.0		4.0 x 6.1	3.8 x 4.6
Motor Size (kW)	610	1600	1350	1500	
Recirculating load (%)	200 – 270	300-400			250
Pulp Density (%)		75		80	75
% Critical Speed			67	78	

The information in Table 2 was then used to develop a set of performance requirements for the Mt Lindsay milling circuit. The work indices in Table 1 were then used to size the rod and ball mills for the performance requirements, using a combination of the industry standard Bond efficiency factors and Rowland/Kjos empirical relationships. Table 3 below outlines the results of these sizing calculations, developed in conjunction with FLS.

Table 3: Summary of proposed milling parameters for Mt. Lindsay grinding circuit

Property	Rod Mill -20mm feed	Rod Mill -15mm feed	Ball Mill
Performance requirements			
Throughput (t/h)	200	200	200 (new feed)
F80 (µm)	14,000	10,000	1,500 (new feed)
P80 (µm)	1,500	1,500	120 (closed circuit product)
Mill sizing calculations			
Mill diameter (m)	3.69	3.69	4.0
Mill length (m)	5.49	5.49	5.8
L:D ratio	1.49	1.49	1.45
Mill volume (m^3)	53.6	53.6	67.1
Recirculating load (%)	-		250
Power at pinion (kW)	788	788	1,214
Installed motor power required (kW)	950	950	1,400
Instantaneous throughput limit (t/h)	217	200	219 (new feed)

Table 3 also highlights how reducing the crushed product from -20mm to -15mm does not affect the required size of the rod mill, and hence the ball mill. The finer feed should, at face value, reduce the size of rod mill required to achieve the target 1,500µm P_{80}. However, the -15mm feed is smaller than the optimum feed size for a rod mill, and the mill performance is shifted towards a region of inefficiency. This inefficiency requires a larger mill to overcome – the net result is an unchanged rod mill size. It is possible that further reductions in mill feed size would require a mill larger again.

BRS therefore recommends targeting a -20mm mill feed.

The details of this behaviour are outlined in Appendix B, which contain the full rod and ball mill sizing calculations.

The SysCAD flowsheet simulation includes process performance models for rod and ball mills (JKTech, 2003). However, the information derived from standard Bond tests is generally insufficient to scale up the laboratory mills to full-size equipment (Morrell and Yan, 1997). Therefore, the mill sizes above were input into the flowsheet simulation and the rod and ball model parameters were manipulated until the performance targets were achieved.

The manipulated parameters were 'sanity checked' against similarly-modelled mills in the BRS database, and the values were found to be of the appropriate order and range.

Whilst this is not a true scale-up process, it does demonstrate the potential for the selected equipment to perform under typical operating conditions, with VML-specific feed sizings, recirculating loads, product sizing etc. True scale-up will require a more complete set of test work information which includes slight modifications to the standard Bond test procedures.

Figure 7 below illustrates how close the potential full-scale circuit product is to the 120µm target product.

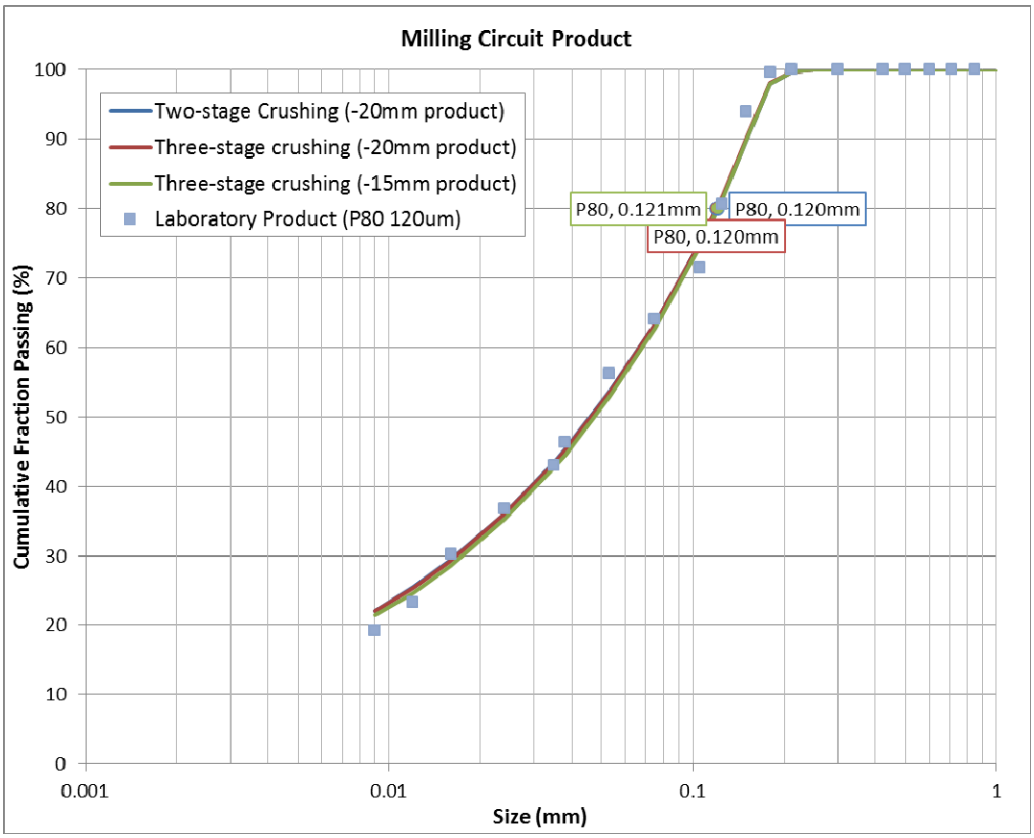

Figure 7: Comparison of estimated grinding circuit product size distribution versus results from laboratory tests

As might be expected, there is very little difference between the milling circuit products originating from alternative crushing circuit arrangements.

Furthermore, the circuit products match the size distribution obtained from the laboratory ball mill test very well. However, as a degree of manual model parameter manipulation was necessary, the

quality of the match should only be taken to be indicative – that is, the milling equipment is potentially capable of achieving the target, but more test work is required to verify this.

A full stream and process summary for each circuit is found in Appendix A. These simulations have been limited to the -800mm Coarse RoM feed for brevity.

Conclusions

- From this order of magnitude investigation of the crushing and grinding requirements for the Mt. Lindsay project, it appears possible to obtain the desired grind size P_{80} of 120µm at an instantaneous rate of 200 tph.
- There are options to use two stage crushing, but in terms of operability and optionality, the three stage circuit appears to offer a more robust and resilient solution.
- The three stage crushing circuit shown in Figure 4 offers the ability to generate a -20mm feed to the grinding mills and possibly a -15mm feed.
- The use of a -15mm mill feed does not reduce the size of the mills as it is below the optimal feed size for the rod mill, compromising throughput and size reduction performance. BRS therefore recommends that -20mm mill feed is used for design.
- A rod/ball milling circuit has been sized to achieve the performance targets from VML. Indications from the simulations suggest that the circuit should be able to achieve the desired process performance.

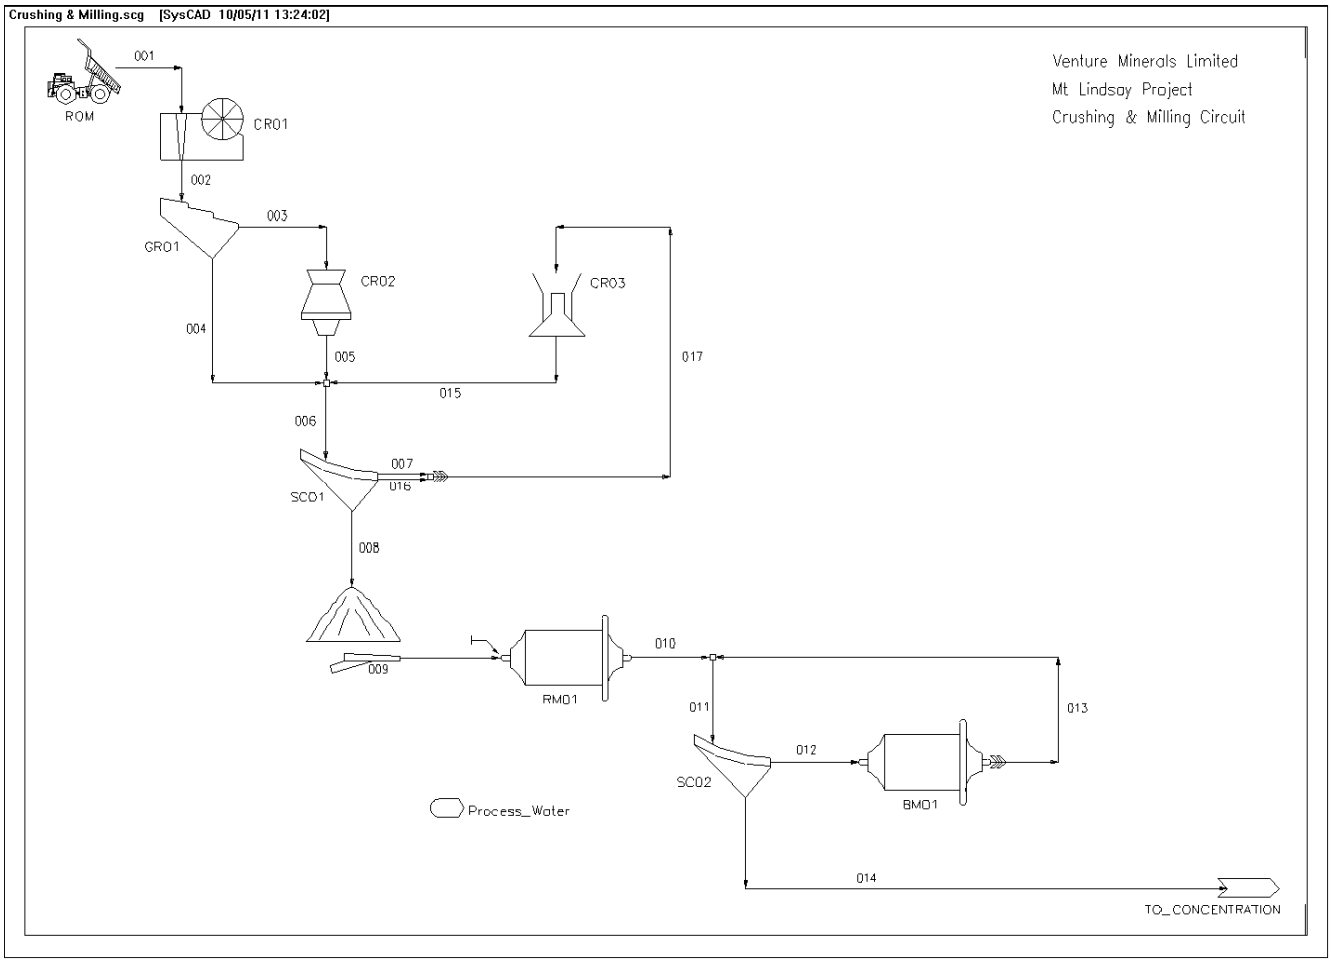
Two Stage Crushing, -800mm Coarse RoM, -20mm product - *Process Summary*



EQUIPMENT SUMMARY		
Property	**Units**	**Value**
CR01		
Feed rate	t/h	308.1
F_{80}	mm	495.6
P_{80}	mm	97.9
Reduction ratio	frac	5.06
Gross Power	kW	64
CR02		
Feed rate	t/h	98.9
F_{80}	mm	89.7
P_{80}	mm	19.5
Reduction ratio	frac	4.60
Gross Power	kW	249
SC01		
Top deck		
Feed rate	t/h	717.4
Load	%	42.9
Efficiency	%	72.5
d_{50}	mm	29.2
Bottom deck		
Feed rate	t/h	407.0
Load	%	57.4
Efficiency	%	87.1
d_{50}	mm	18.4
SC02		
Feed rate	t/h	906.1
Load	%	
Efficiency	%	
d_{50}	mm	
RM01		
Feed rate	t/h	205.4
F_{80}	mm	13.92
P_{80}	mm	1.49
Reduction ratio	frac	9.34
Gross Power	kW	858
BM01		
Feed rate	t/h	476.1
F_{80}	µm	724.6
P_{80}	µm	394.6
Reduction ratio	frac	1.84
Gross Power	kW	1,329
Recirculating load	%	237

Note: #2 Skarn Bond Ball test used a closing screen size of 106µm, resulting in a P80 of 75µm – below the 120µm circuit target.

Three Stage Crushing, -800mm Coarse RoM, -20mm product – *Flowsheet*

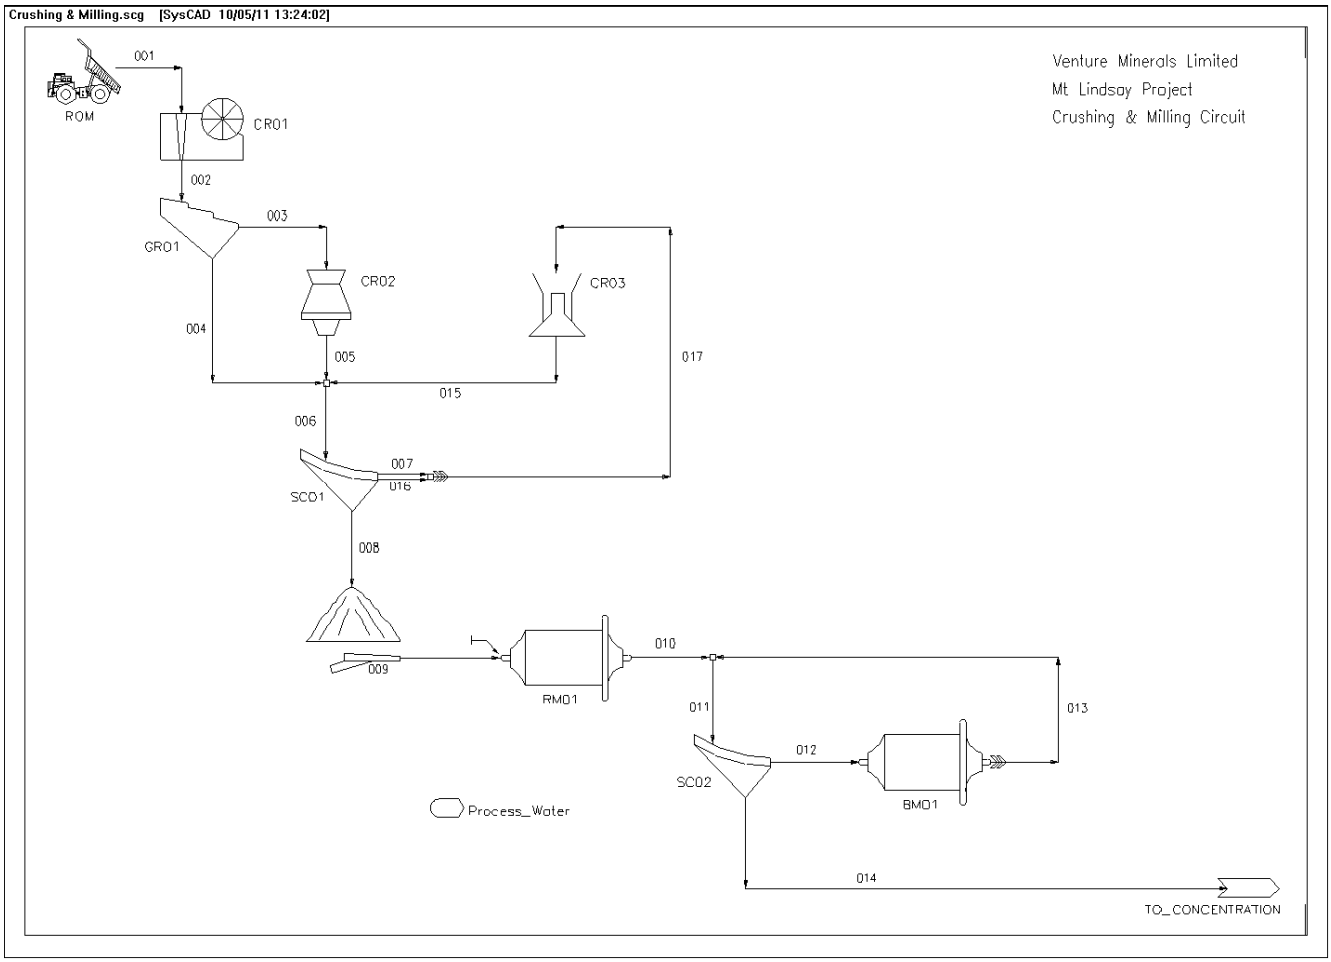
Three Stage Crushing, -800mm Coarse RoM, -20mm product - *Process Summary*



EQUIPMENT SUMMARY		
Property	**Units**	**Value**
CR01		
Feed rate	t/h	308.1
F_{80}	mm	495.6
P_{80}	mm	97.9
Reduction ratio	frac	5.06
Gross Power	kW	64
CR02		
Feed rate	t/h	204.5
F_{80}	mm	110.9
P_{80}	mm	25.9
Reduction ratio	frac	4.28
Gross Power	kW	114
Gross Power	HP	152
CR03		
Feed rate	t/h	363.8
F_{80}	mm	25.1
P_{80}	mm	21.8
Reduction ratio	frac	1.15
Gross Power	kW	76
Gross Power	HP	102
Recirculating load	% solids	118
GR01		
Feed rate	t/h	308.1
Load	%	78.4
Efficiency	%	94.4
d_{50}	mm	37.0
SC01		
Top deck		
Feed rate	t/h	204.5
Load	%	48.6
Efficiency	%	79.4
d_{50}	mm	24.6
Bottom deck		
Feed rate	t/h	100.9
Load	%	52.5
Efficiency	%	83.3
d_{50}	mm	18.3
SC02		
Feed rate	t/h	883.5
Load	%	
Efficiency	%	
d_{50}	mm	
RM01		
Feed rate	t/h	205.4
F_{80}	mm	14.37
P_{80}	mm	1.49
Reduction ratio	frac	9.65
Gross Power	kW	858
BM01		
Feed rate	t/h	506.9
F_{80}	µm	700.3
P_{80}	µm	396.3
Reduction ratio	frac	1.77
Gross Power	kW	1,329
Recirculating load	% solids	252

Note: #2 Skarn Bond Ball test used a closing screen size of 106µm, resulting in a P80 of 75µm – below the 120µm circuit target.

Three Stage Crushing, -800mm Coarse RoM, -15mm product – *Flowsheet*

TECHNICAL NOTE

Ammonium Paratungstate (APT): is a white, finely divided, crystalline material. It is produced by evaporation of purified ammonium tungstate solution to obtain pure paratungstate crystals. Controls of time, temperature, concentration, and pH, determine the quality and physical characteristics of the ammonium paratungstate crystals.

Modern processing methods dissolve scheelite or wolframite concentrates by an alkaline pressure digestion, using either a soda ash (Na_2CO_3) or caustic (NaOH) solution. The sodium tungstate solution obtained then undergoes an impurity removal step using either a hydrochloric acid wash or an ion exchange resin to produce tungstic acid. The tungstic acid is converted into ammonium tungstate by the addition of ammonia causing the ammonium tungstate to evaporate which is then cooled and precipitated into high purity Ammonium-Paratungstate (APT) with the formula $5(NH_4)_2O.12WO_3 \cdot 5H_2O$.

The above formula for APT is non-stoichiometric. With respect to tungsten in the trioxide form, a series of related materials that are slightly deficient in oxygen can be generated. Also, the non-stoichiometric description $WO_{2.98}$ for "blue" tungsten oxide implies a random distribution of oxide valencies.

The basic chemistry for production of APT and "blue" and "yellow" tungsten oxide from Scheelite is as follows:

Scheelite ($CaWO_4$)
(ground to -53μm)

↓

Leaching
(under temperature and pressure)

$$Na_2CO_3 + CaWO_4 \longrightarrow Na_2WO_4 + CaCO_3$$

↓

Impurity Removal
(either by Hydrochloric Acid or Ion Exchange)

$$2HCl + Na_2WO_4 \longrightarrow H_2WO_4 + 2NaCl$$

↓

Precipitation
(production of ammonium tungstate)

$$2(NH_4OH) + H_2WO_4 \longrightarrow (NH_4)_2WO_4 + 2H_2O$$

↓

Evaporation
(production of ammonium tungstate)

$$(NH_4)_2WO_4 \xrightarrow{\text{evaporation}} 5(NH_4)_2O.12WO_3 \cdot 5H_2O$$

↓

Calcination
(calcining ammonium tungstate)

$$5(NH_4)_2O.12WO_3 \cdot 5H_2O \xrightarrow{\text{calcine @ } 500^oC} WO_{2.98} \text{ ("blue") or } WO_3 \text{ ("yellow")}$$

Central South University (CSU), Changsha: On Tuesday 23rd November, Professor Zhang introduced me to Professor Xiao Liansheng from CSU's School of Metallurgical Science and Engineering, Institute of Rare Metals Metallurgy.

CSU is one of the more reputable universities in minerals engineering, ferrous and non-ferrous, throughout China. Amongst the others present, there were also two engineers from CHALCO (also known as Chaleco). Only Mr. Heng Shaoting, Vice-General Manager, had a business card and required translated communication.

CHALCO undertake the engineering required by Professor Xiao. Their expertise is more in bauxite/alumina/aluminium having recently undertaken the feasibility into the AURUKUN project located in far northern Queensland. As a result, they understand the engineering methodology and requirements to complete an Australian project.

Initially I was wondering why a company whose primary expertise is in the aluminium industry be present at this meeting. However, Professor Xiao outlined that he has recently patented a new alkaline process for the dissolution of scheelite at higher pressure and temperature which enables increased waste water and caustic soda recovery and an easier separation between tungsten and molybdenum. The conditions outlined are similar to a bauxite digestion. Then he also highlighted a calcination stage at a temperature of ~500 degrees Celsius for manufacturing APT into either "blue" or "yellow" oxide powders. Calcination is also a major part of the alumina refining process, so the connection between CHALCO and CSU is logical.

Professor Xiao indicated that CSU has designed more than 12 APT plants in China with tungsten being sourced from scheelite and wolframite concentrates of various grades and spent materials. They have also recently been utilising an ion exchange step as a replacement for hydrochloric acid which has enabled a higher purity APT to be produced. For a similar scale plant to what Venture is contemplating, say between 3,500 – 5,000 tpa, overall capital cost is roughly expected to be ~150 million RMB. The HCl route has an operating cost of 10,000 RMB/t feed. The ion exchange process can substantially reduce operating cost to 6,000 RMB/t.

For testwork purposes, a minimum of 2kg of scheelite concentrate is required. However, this represents quite a substantial amount for Venture and will require a final process validation bulk sample (maybe of 1.0 to 1.2 tonnes) in order to provide an indicative scheelite concentrate to conduct APT testwork on. As a preliminary guide, a "desktop" study can be undertaken by CSU by Venture providing the final concentrate specification and mineralogy to CSU following the proposed testwork to be undertaken at GZRINM.

SUMMARY

A defined program of metallurgical testwork was carried out on composites of ore representing the Mt Lindsay Deposit, in Tasmania.

Salient test data are presented below:

• Head Assays

HEAD ASSAYS							
Composite	WO3 (%)	Cu (ppm)	Fe (%)	S (%)	SiO_2 (%)	Sn (ppm)	Soluble Sn (ppm)
MacDonald Composite	0.18	578	30.7	4.96	24.2	4150	800
Radford Composite	0.42	726	33.8	3.62	23.8	1500	520
Ore Type 3	0.34	700	34.2	3.35	23.7	2800	800

• Comminution Testwork

The Radford Composite was submitted for Bond rod and ball mill work index testing.

a) Bond Rod Mill Work Index

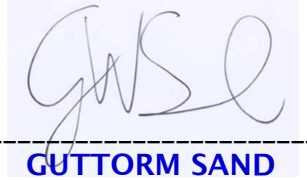
1. INTRODUCTION



Messrs Geoff Beros and Jason Amaranti, representing Venture Minerals (VML), requested that ALS Ammtec undertake a metallurgical program of pilot grinding, magnetic separation and flotation testing of two composites from the Mt Lindsay mine site. The aim of the program was to produce bulk concentrate and tailings samples for vendor testing.

The metallurgical test work conducted included the following:

- Preparation and sub-sampling of two bulk composites (McDonald Skarn and Radford Composites) to be treated in the pilot plant, with the sub-samples used for:
  - Head and size analysis
  - Comminution testwork
  - Sighter LIMS testwork
  - Base-line flotation testing
- Pilot scale magnetic separation and flotation of each of the samples to produce sulphide concentrates and low sulphide tailings.
  - Control Assays, Surveys and Size Analysis.
- Recovery, analysis and storage of concentrate samples and tailings for vendor testing and disposal.

The testwork was controlled by Mr Geoff Beros on behalf of Venture Minerals Limited. Guttorm Sand supervised the program on behalf of ALS Ammtec. Test results were communicated between ALS Ammtec and the client as they became available, in this way the program progressed on a fully informed basis.

RON GROGAN
Chief Executive – Metallurgy

GUTTORM SAND
Senior Metallurgist

2. THE SAMPLES

ALS Ammtec was requested by the client to retrieve samples stored under a previous Job No. A13128. The samples represented the Mt Lindsay Deposit located in the Tasmania.

- MacDonald Composite
- Radford Skarn Composite

The above composites were then combined in an approximate 50/50 blend to produce a third composite labelled Ore Type 3.

The MacDonald Composite was already prepared, however additional blending and crushing was conducted where required. The test work flow sheet is presented in Figure 1.

Radford Skarn Composite and Ore Type 3 Composite recipes and sample inventories are included in Figures 2 and 3.

3. SAMPLE PREPARATION

Each generated composite sample was prepared according to the flowsheets presented in the Figures.

Each composite sample was control crushed to 100% passing <3.35 mm and thoroughly homogenised by passing three times through a rotary sample splitting device and split into sub-samples for further grinding as required for the testwork program.

3.1 Testwork Water

Perth tap water was used for all facets of the test program whereby wet grinding and slurry preparation was required.

4. ANALYTICAL

All assay samples, generated during the course of the test program, were submitted to ALS Ammtec's assay laboratory for analysis.

The following analytical methods were employed:

Elements:	Mixed acid digestion/ICP-MS
Acid soluble Sn:	HF acid digest/ICP-MS

5. HEAD ASSAYS

Comprehensive head assay results are presented in Appendix I while a summary of results is shown in the following table:

HEAD ASSAYS							
Composite	WO3 (%)	Cu (ppm)	Fe (%)	S (%)	SiO_2 (%)	Sn (ppm)	Soluble Sn (ppm)
MacDonald Composite	0.18	578	30.7	4.96	24.2	4150	800
Radford Composite	0.42	726	33.8	3.62	23.8	1500	520
Ore Type 3	0.34	700	34.2	3.35	23.7	2800	800

6. COMMINUTION TESTWORK

The Radford Composite was submitted for Bond rod and ball mill work index testing.

6.1 Bond Rod Mill Work Index

6.1.1 Test Procedure

The Radford Composite was tested using the standardised procedure detailed by F.C. Bond[1] to determine its Bond rod mill work index.

The test procedure was as follows:

(1) The test sample was stage crushed to 100% passing 12.5 mm and test portions were rotary split for the work index test.

(2) A known volume of ore (1250 ml) was ground in the standard mill for a counted number of revolutions.

(3) The ground material was screened at a test aperture of 1 180 µm to remove the -1 180 µm material.

(4) Fresh feed was added to the +1 180 µm fraction to make up to the original test weight.

(5) The number of mill revolutions was adjusted at each cycle until a stable recirculating load was achieved.

[1] Bond, F.C. "Crushing and Grinding Calculations" (1961) British Chemical Engineering, Vol 6, Nos 6, 8

(6) The work index was calculated from the formula:

$$(Wi)_R = \frac{62.0}{(Pi)^{0.23} \times (Grp)^{0.625} \times \left(\frac{10}{\sqrt{P_{80}}} - \frac{10}{\sqrt{F_{80}}}\right)} \times 1.102$$

Where:

$(Wi)_R$	=	Work index value expressed in kWh/tonne
Pi	=	Grindability test aperture (micrometres)
Grp	=	Mean of equilibrium grindability values (g/rev)
P_{80}	=	80% passing size of the equilibrium product (micrometres)
F_{80}	=	80% passing size of the feed to period 1 (micrometres)

6.1.2 Test Results

BOND ROD MILL WORK INDEX					
Sample Identity	Micrometres		Grp (g/rev)	Test Aperture Pi (µm)	Bond Rod Mill Work Index (kWh/t)
	F_{80}	P_{80}			
Radford Composite	8812	668	4.408	1180	19.0

Detailed Bond rod mill work index test data are presented in Appendix II.

6.2 Bond Ball Mill Work Index

The Radford Composite was tested using the standardised procedure detailed by F.C. Bond[2] to determine the Bond ball mill work index of the sample at a closing screen size of 106 µm.

6.2.1 Test Procedure

The test procedure was as follows:

(1) The sample was stage crushed to 100% passing 3.35 mm and test portions rotary split out for the work index test.

(2) A known volume of ore (700 ml) was ground in the standard mill for a counted number of revolutions.

(3) The ground material was screened at a test aperture of 106 µm to remove the -106 µm screen undersize material.

[2] Bond, F.C. "Crushing and Grinding Calculations" (1961) British Chemical Engineering, Vol 6, Nos 6, 8

(4) Fresh feed was added to the +106 µm screen oversize fraction to make up to the original test mass.

(5) The number of mill revolutions was adjusted at each cycle until a stable recirculating load was achieved.

(6) The work index was calculated from the formula:

$$(Wi)_B = \frac{44.5}{(Pi)^{0.23} \times (Gbp)^{0.82} \times \left(\frac{10}{\sqrt{P_{K80}}} - \frac{10}{\sqrt{F_{K80}}} \right)} \times 1.102$$

Where:

$(Wi)_B$ = Work index value expressed in kWh/tonne

Pi = Grindability test aperture (micrometres)

Gbp = Mean of equilibrium grindability values (g/rev)

P_{80} = 80% passing size of the equilibrium product (micrometres)

F_{80} = 80% passing size of the feed to period 1 (micrometres)

6.2.2 Test Results

Grindability test data and the calculated work index values are presented below:

BOND BALL MILL WORK INDEX					
Sample Identity	Micrometres		Gbp (g/rev)	Test Aperture Pi (µm)	Bond Ball Mill Work Index (kWh/t)
	F_{80}	P_{80}			
Radford Composite	2571	81	1.356	106	14.4

Detailed Bond ball mill grindability test report sheets are presented in Appendix III.

7. SIGHTER TESTWORK

7.1 Wet Low Intensity Magnetic Separation (LIMS)

Sighter wet LIMS separation was carried out on each composite at grind size P_{80} 125 µm. The magnetics and non-magnetics for each were assayed in detail.

7.1.1 Test Procedure

The test procedure was as follows:

(1) Each sample was stage ground to a grind size P_{80} approximately 125 µm.

(2) Using a hose, the milled sample was slowly washed into an *Eriez L8* LIMS separator set at 600 gauss (operated co-currently).

(3) The wet LIMS magnetics were recovered and passed through the magnetic separator for two additional passes at increasing magnetic field of 900 and 1200, gauss for the second and third pass..

(4) The LIMS magnetics and non-magnetics were recovered. Each product was dried, weighed and sub-sampled for assay.

(5) From the wet LIMS test data, the weight and elemental distribution were calculated.

7.1.2 Test Results

LIMS results are included in Appendix IV while a summary has been included below:

SIGHTER LIMS SIGHTER TESTWORK								
Sample Id	Product	LIMS Fractions Grade/Distribution						
		Mass (%)	Sn		WO3		S	
			(%)	Dist'n (%)	(%)	Dist'n (%)	(%)	Dist'n (%)
MacDonald Composite*	Combined Mag Con	6.06	0.14	1.13	0.02	0.44	8.06	8.89
	Non-Mag	93.9	0.77	98.9	0.29	99.6	5.33	91.1
Radford Composite	Combined Mag Con	29.0	0.04	7.94	0.05	2.93	3.99	35.1
	Non-Mag	71.0	0.20	92.1	0.73	97.1	3.02	64.9
Ore Type 3	Combined Mag Con	40.4	0.12	21.8	0.14	22.6	5.44	64.9
	Non-Mag	59.6	0.30	78.2	0.33	77.4	1.99	35.1

* 2-stage pass at 900G each stage

7.1.3 Comments

- LIMS sighter work indicated that the Radford composite and also Ore Type 3 could remove more mass to the magnetic fraction than the MacDonald Composite.
- In all three tests most of the tungsten reported to the non-magnetic fraction.
- The lower tin and tungsten recovery to the non-magnetic fraction in Ore Type 3 could possibly be due to entrainment. This may explain the higher mass removal to the magnetic fraction compared with the other two composites.

7.2 Flotation Testwork

The non-magnetic fractions from sighter LIMS testwork were submitted for bench scale sulphide flotation testwork.

7.2.1 Test Procedure – Bench Flotation

Non-magnetic samples were subjected to standard bench scale flotation. The testing procedure included:

(1) The non-magnetic sample was transferred to the laboratory *Agitair* LA500 flotation machine (2.2-litre cell) and adjusted to a pulp density of approximately 35% solids (w/w). The tests were conducted using a machine speed of 1000 rpm unless otherwise stated.

(2) Slurry pH and ORP were measured at each flotation stage.

(3) Reagents were added as per the reagent scheme supplied by the client. Collector was added incrementally by syringe to the desired dosage. Frother was added in drops from an eye-dropper (one drop estimated at 12 g/t).

(4) Flotation air was introduced manually into the flotation cell to achieve the optimum froth – depending on the stage of the test. A scraper using a set pattern of approximately 10 strokes per minute removed froth manually.

(5) The flotation tests were conducted using the flowsheet, reagent scheme, conditioning times and froth removal times as shown in each results table.

(6) Each flotation product was filtered, dried and weighed before being submitted for analysis.

7.2.2 Test Results – MacDonald

Each flotation test was completed under the following flotation conditions:

- GWS0227 : 50 g/t PAX, 100 g/t SIBX, 150 g/t $CuSO_4$, 3 Cons
- GWS0230 : As per GWS0227, 6 cons
- GWS0229 : 150 g/t PAX, 150 g/t $CuSO_4$
- GWS0245 : As per GWS0229, DI water
- GWS0246 : 150 g/t PAX, 250 g/t $CuSO_4$
- GWS0247 : 250 g/t PAX, 250 g/t $CuSO_4$

The results from this test have been summarised and are presented in the table that follows. Detailed test data are provided in Appendix V.

MacDONALD BENCH-SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO3		S	
		(%)	Dist'n (%)	(%)	Dist'n (%)	(%)	Dist'n (%)
GWS0227	91.1	0.53	97.2	0.22	96.8	2.11	51.7
GWS0230	91.5	0.57	97.6	0.22	97.1	2.09	47.6
GWS0229	91.5	0.56	97.6	0.23	97.0	1.90	45.9
GWS0245	90.0	0.54	97.0	-	-	2.20	47.1
GWS0246	87.4	0.54	95.7	-	-	2.18	48.7
GWS0247	84.9	0.57	95.0	-	-	1.36	30.0

7.2.3 Comments

The aim of the float sighter tests was to remove as much sulphur (S) as possible from the sample whilst keeping as much tin (Sn) and tungsten (WO3) in the tails as possible. The sighter tests only managed to get the sulphur grade down to 1.36%, however in the pilot, a sulphur grade of less than 0.5% was achieved.

7.2.4 Test Results - Radford

Each flotation test was completed under the following flotation conditions:

- GWS0348 : 250 g/t PAX, 250 g/t $CuSO_4$
- GWS0349 : 350 g/t PAX, 250 g/t $CuSO_4$
- GWS0350 : 150 g/t PAX, 150 g/t $CuSO_4$

The results from this test have been summarised and are presented in the table that follows. Detailed test data are provided in Appendix VI.

RADFORD BENCH-SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO3		S	
		(%)	Dist'n (%)	(%)	Dist'n (%)	(%)	Dist'n (%)
GWS0348	89.1	0.22	97.8	-	-	0.87	25.1
GWS0349	90.2	0.21	98.1	-	-	1.19	34.2
GWS0350	89.3	0.23	98.2	-	-	0.87	25.0

7.2.5 Comments

- The sighter test work indicated that sulphur grades below 1% in the tail could be achieved. It also indicated that the majority of the tin remained in the tail.

7.2.6 Test Results – Ore Type 3

Each flotation test was completed under the following flotation conditions:

- GWS0578 : 350 g/t PAX, 250 g/t $CuSO_4$
- GWS0579 : 250 g/t PAX, 250 g/t $CuSO_4$
- GWS0580 : 150 g/t PAX, 150 g/t $CuSO_4$

The results from this test have been summarised and are presented in the table that follows. Detailed test data are provided in Appendix VII.

ORE TYPE 3 BENCH-SCALE FLOTATION							
Float Test No	Tail Product Grade/Distribution						
	Wt (%)	Sn		WO3		S	
		(%)	Dist'n (%)	(%)	Dist'n (%)	(%)	Dist'n (%)
GWS0578	87.2	0.33	94.7	0.40	94.3	0.19	8.09
GWS0579	85.1	0.32	93.1	0.45	93.0	0.17	7.12
GWS0580	85.5	0.34	93.7	0.36	93.4	0.18	7.37

7.2.7 Comments

- The sighter work for the Ore Type 3 Composite indicated that most of the sulphur was floated whilst keeping the majority of the tin and tungsten in the tail.

8. IsaMILL SIGNATURE PLOT AND REGRIND WORK ON MAGNETIC CONCENTRATE

The IsaMill™ marketed by Xstrata Technology can be accurately scaled up from testwork conducted in a laboratory IsaMill (4 Litres). Provided that the media and pulp conditions used are representative of that which will be used and processed in the plant, the scale up using a signature plot can be done directly.

The power and product size distribution have very accurate scale up provided conditions stated above are met. This is due to the fact that the ore particle in an IsaMill is subjected to similar grinding conditions irrespective of the IsaMill size. The power is measured at the agitator shaft to determine the power requirements.

Keramax MT1 is the media of choice by Xstrata for signature plot testing but other media types can be tested at the clients' request.

Once the signature plots were conducted regrind work was performed on all three composites and a SLON product. The regrind times were based on the results from the signature plots.

8.1 Test Procedure

General procedure for signature plot determination:

(1) Mill feed is put into an agitated tank and made up to desired pulp density (60% solids if not specified otherwise). Feed is recirculated in the tank and desired flowrate set (~2-3l/min typical). Desired flow rate is achieved in order to get target kWh/t energy input

(2) After running mill empty to bring to operating temperature and conduct no-load power run, 2.5L of weighed selected media (Cenotec 5 mm conditioned charge) is added to mill chamber.

(3) Feed is then directed to the mill and after approximately 5 seconds, the mill is switched on at 1500 rpm (nominal). At this time the cumulative power is recorded at stopwatch started.

(4) At the midpoint of the run, samples are taken for sizing and percent solids checks and measurements are taken of the pulp density (by Marcy) and slurry flowrate.

(5) As soon as the feed tank is empty, the mill and timer is stopped. Both the time taken and the total power consumption (Wh) is recorded for all the slurry to be treated through the mill.

(6) This process is repeated until required energy input or required product fineness is achieved (generally 5 to 6 cycles).

(7) At the end of test, the mill is emptied and then run with an empty chamber again to get a second no-load power reading. If required, the media is also cleaned and reweighed to determine media consumption.

8.2 Test Results

A summary of the calculated specific energy at the desired grind size is given below. For full signature plot details, refer to Appendix VIII.

IsaMill SIGNATURE PLOT			
Sample Identity	**Media**	**Applied Energy (kWh/t)**	**Target P_{80} Size (µm)**
Radford Composite Mag Concentrate	Cenotec 5 mm Graded Charge	23.2	45
MacDonald Composite Mag Concentrate		24.9	45

8.3 Regrind Results (Regrind Work Conducted on Magnetic Concentrate Products)

A summary of the average P_{80} size of reground magnetic concentrate is given below. For full details, refer to Appendix VIII.

REGRIND RESULTS	
Sample Identity	**Average P_{80} (µm)**
MacDonald Composite – Mag Concentrate	47.8
Radford Composite – Mag Concentrate	44.5
Ore Type 3 – Mag Concentrate	44.9
SLON Product	28.6

9. PILOT PLANT TESTWORK

Pilot scale magnetic separation and flotation of each of the samples to produce sulphide concentrates and low sulphide tailings.

9.1 Wet Low Intensity Magnetic Separation (LIMS)

Pilot plant scale wet LIMS separation was carried out on each composite at grind size P_{100} 180 µm. The magnetics and non-magnetics for each were assayed in detail.

9.2 Flotation Testwork

The non-magnetic fraction from LIMS testwork was submitted for pilot scale sulphide rougher flotation. The reagent conditions were as a follows:

- $CuSO_4$: 150 g/t
- SIBX : 100 g/t
- PAX : 500 g/t

Each flotation concentrate and the final tailings were assayed in detail.

9.3 MacDonald Pilot Results

The MacDonald pilot results, including comprehensive size by size assay results, are presented in Appendix IX. A summary of selected results are shown in the following tables:

Flotation Flowsheet , Reagent Scheme & Results - **Test : Flotation**

TEST DETAILS :

PROJECT	A13718 - Mt Lindsay (Venture Minerals)
COMPOSITE	**MacDonald Skarn**
PILOT STAGE	Flotation
WATER TYPE	**TAP WATER**
GRIND SIZE	P80= As supplied
PULP DENSITY	
TECHNICIAN/DATE	5/09/2011

Cassiterite Liberation Analysis

of

Mt. Lindsay Ore

for

Venture Minerals

ESKER Milling & Processing Pty Ltd

Report: **Cassiterite Liberation Analysis For The Mt. Lindsay Ore Body**

TO: Geoff Beros
General Manager Metallurgy
Venture Minerals
Freemasons Hall
WEST PERTH WA 6872
Australia

Subject: Carry out a release analysis for cassiterite using gravity and magnetic separation on a scheelite flotation tailing taken from a combined sample of Mt Lindsay's two main ore types. This work will determine at what size the cassiterite is liberated. It will also establish what grade concentrate can be produced by using gravity, with and without using magnetic separation.

By: Nick Moony

SUMMARY

This report involved a program of gravity and high gradient magnetic separation as well as stereomicroscopic examinations of selected products. The investigation was carried out on tailings taken on a whole ore flotation test for scheelite (WOFT) from a blended sample of Mt. Lindsay's two major primary ore types. The object was to establish the liberation characteristics for cassiterite and to identify potential processing routes for recovering tin. In this investigation soluble tin content was not assayed because of the problems ALS were having in setting up a new assaying service that was reliable and timely at their Burnie laboratory. The program of work established the following:

- The high gradient magnetic separation test work carried out on this sample in Perth did not work very well because up to 88% of the material is magnetic at about 8,500 gauss.

- The cassiterite grain size is fine and major cassiterite liberation does not occur until about 106µm, therefore, it is very unlikely that conventional gravity recovery separation will ever be viable for processing this ore on its own as it was found that:

- On a primary grind of 80% passing 120µm the cassiterite liberation at different sizes is shown below:

    - At 150µm 10.0%
    - At 106µm 48%
    - At 75µm 64%
    - At 53µm 82%
    - At38µm 85%
    - At 26µm >95%
    - Overall liberation ≈ 72%

- Because significant cassiterite liberation does not start until the ore is ground to 80% passing 120µm and then complete liberation is only gradually reached, it very likely that conventional gravity separation on this sample of ore will only recover 30% to 40% of the cassiterite into a high grade gravity concentrate assaying >60% Sn.

- Tin minerals do not slime which means that the tin loss in any de-sliming operation before cassiterite flotation will be low.

- It is difficult to achieve acceptable concentrate grades of >60% Sn without the help of magnetic separation.

- It was found that at least 15% to 20% of the cassiterite has magnetic inclusions, but this cassiterire can be recovered into gravity concentrates assaying between 35% and 40% Sn.

- Magnetic separation used directly on WOFT before gravity separation will incur significant tin losses as high as 25% on coarser fractions.

- In this investigation a reject tailing grade of <0.10% Sn was aimed for and achieving this grade did not occur until the 53µm fraction was reached

- Nevertheless magnetic separation carried out on gravity tails allows for at least 50% of the weight in the WOFT to be rejected at acceptable tailings grades of less than 0.14% Sn in >38µm fractions.

- Rejection of tailings at grades of 0.14% Sn then becomes an economic decision and must involve an investigation into what tin recovery can be expected, from what must be very fine particles of composite cassiterite in the >53µm tails.

- If gravity tailings are reground to say 80% passing 53µm, then using magnetic separation before cassiterite flotation may be beneficial in several ways.

- A small amount of coarser free scheelite reported to WOFT and only assayed 0.03% WO3. This scheelite is readily recoverable by gravity separation and can be separated from the cassiterite by electro static separation, as the scheelite is mostly coarser than 75µm.

- It is also interesting to note that even a small amount of scheelite in a panned concentrate can be easily over estimated if UV light is used to judge the scheelite content.

- Common heavy minerals indentified include, magnetite, scheelite, pyrite, pyrrhotite, siderite and various amboils.

Introduction

In February 2012 a sample of high gradient non-magnetics, generated after the recovery of magnetite and the removal of sulphides in Perth, was sent to ALS metallurgical laboratory in Burnie (BRL). The sample received at BRL was then divided into 2kg lots and subjected to whole ore flotation for scheelite. The first two tails from this programme of work were then combined and subjected to a release analysis for cassiterite by panning using a vanning plaque, and magnetic separation using a dry Rapid cross belt separator on a size-by-size basis

Panning is one of the best ways to determine the economic potential of oxide minerals when treating smaller sample lots for minerals such as wolfram, scheelite, cassiterite, tantalum and rare earths. Panning on a size-by-size basis defines a grade recovery curve, liberation size, variability between ore zones, potential concentrate grades, contaminates and regrinding requirements.

Earlier work had found that at least 85% of Mt. Lindsay known ores is para magnetic. One of the aims of this report was to determine if and how high gradient magnetic separation can be used beneficially and, in this instance, it was thought that a dry Rapid magnetic separator would determine the magnetic content down to 26µm, and it is normally an excellent guide on how a high gradient wet magnetic separator would perform, especially when processing small samples. All tests were conducted at about 8,500 gauss and at the same cross belt rotor settings.

The tailings from the first two WOF scheelite flotation tests were amalgamated, thoroughly mixed, sized at 150µm, 106µm, 75µm, 53µm, 38µm, 26µm, 20µm, 15µm, 10µm and 5µm. The <5µm cylosizer over flow was collected, all fractions were assayed and >20µm fractions processed.

The aim of this report was to see how a high gradient magnetic could be used beneficially in maximizing tin recovery and concentrate grade. It was hoped to demonstrate this by using magnetic separation on some fractions and not on others, and In addition subjecting various gravity products to magnetic separation.

1 - Discussion of Results

1.1 - Preparation for Panning and High Gradient Dry Magnetic Separation

The sample received at BRL in early February 2012 had been oven dried. It was then divided into lots weighing about 1,700 grams and was subjected to whole ore flotation (WOF) for scheelite. Results are given below in **Table One** and **Table Two**.

Table One
WOF Test One

Comments

The WOFT sizing **Table Three** shows that tin distribution indicates that cassiterite is harder and more resilient than any other mineral, only 3% of the tin reports to the <5µm fraction. The high WO3 assay may be due to the small amount of tungsten oxide present in the ore. These fine minerals occur as trace amounts in most tungsten ore bodies. In **Figure One** the skewed tin distribution is clearly seen.

Figure One
WOFT Tin Distribution

2 – Panning and Magnetic Separation

2.1 – 150µm Performance

Table Four
Mozley Performance 150µm

>150µm Balance											
				Assays				Disribution			
	Product	Wt	Wt%	Sn%	WO3%	Fe%	S%	Sn%	WO3%	Fe%	S%
	>150µm Panned Conc	1.29	0.62	14.95	2.82	20.00	7.37	33.3	65.0	0.8	11.9
	>150µm Middlings	16.63	7.92	0.47	0.06	6.03	0.54	13.5	17.8	3.1	12.1
	>150µm Tailing	192.08	91.46	0.16	0.01	16.00	0.31	53.2	17.2	96.1	76.0
	> 150µm Fraction	210.00	100.00	0.28	0.03	15.23	0.35	100.0	100.0	100.0	100.0
	Assay			0.37	0.03	15.00	0.40				

Comments

The panning performance was poor for tin and good for tungsten even though the WO3 grade is very low, and if any WO3 losses were to occur in the WOF process it would be in these coarse sizes.

				0.37	0.03	15.00	0.40				

Comments

It can be seen that complete cassiterite liberation was poor in this fraction as shown in **Table Five** and it is likely that about 5% of the cassiterite is completely free as seen under the microscope. The concentrate was observed to be mixed with sulphides and composites of cassiterite, siderite and amphiboles? Scheelite was observed as a major mineral both with the microscope and especially when observed under the UV light.

Gravity separation was carried out aiming for a rejectable tailings assaying at <0.10% Sn; as can be observed this was not achieved for this fraction. Rejection of the tails is an economic decision, because even at this coarser size some 91% of the weight can be rejected at 0.16% Sn. This alternative proposition becomes more relevant when taking grinding costs into consideration. **Figure Three** shows 91% of the weight reports to the fine composite and **Figure Four** clearly shows that very little if any of the tin in these fractions can be considered rejectable, but preferential tin distribution distorts the head grade as the fraction feed assays 0.37% Sn and the overall feed assays 0.67% Sn.

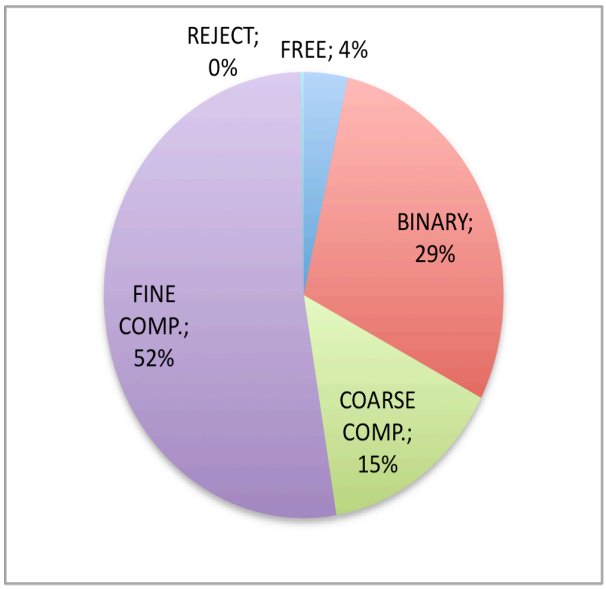
150µmn - Wt% Distribution 1



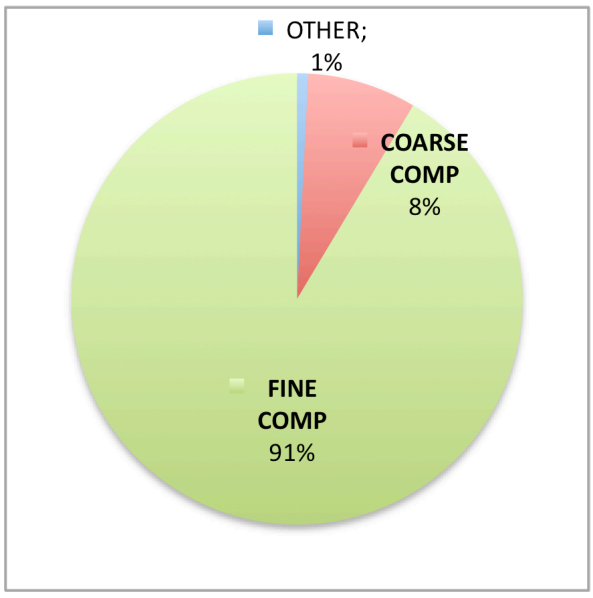


Figure Four
50µm Tin Distribution

2.2 - 106µm Performance

Table Six
106µm Mozley Performance

>106µm Balance											
	Mozley Performance			Assays				Disribution			
		Wt	Wt%	Sn%	WO3%	Fe%	S%	Sn%	WO3%	Fe%	S%
	>106µm Mozley Conc	33.14	5.56	4.35	0.51	30.40	0.72	61.8	80.2	9.4	15.4
	>106µm Mozley Middlings	130.37	21.82	0.25	0.03	19.5	0.37	13.3	18.0	23.0	29.7
	>106µm Mozley Tail	433.75	72.62	0.134	0.01	16.7	0.20	24.9	1.8	67.6	54.9
	>106µm Fraction	597.26	100.00	0.39	0.04	17.98	0.26	100.0	100.0	100.0	100.0
	Assay			0.49	0.07	16.85	0.35				

Comments

Recovery to the Mozley concentrate was reasonable and it was attempted to produce a rejectable tail (<0.10 % Sn) with the Mozley by maximising middlings production; as can be seen in **Table Six** this was not achieved. The Mozley concentrate was panned directly and both the Mozley middlings and tails were subjected to magnetic separation on the dry Rapid.

Table Seven
106µm Mozley Concentrate Cleaning

>106µm Mozley Conc			Assays				Disribution

>106µm Panned Tail	27.60	83.28	0.07	<0.01	2.81	0.12	1.2	0.8	7.7	11.5
Pan Feed	33.14	100.00	4.35	0.51	30.40	0.72	100.0	100.0	100.0	100.0

Comments

Observing the Mozley concentrate under the microscope it was felt that a high-grade concentrate could be produced. While clean dominant free cassiterite was observed in the panned concentrate, considerable free sulphides were present as well as siderite and some heavy ampboils which prevented a clean separation as seen in **Table Seven**. The WO3 assay says that there was only 3.87% WO3 but observation under the UV light misidentified it as a major component. When panning the cleaner tail no cassiterite was observed and the test was abandoned.

Mag Sep. Feed	433.75	100.0	0.13	0.01	16.98	0.20	100.0	100.0	100.0	100.0

Comments

The middlings and tails were magnetically separated at about 8,500 gauss. "Binary" cassiterite/siderite, cassiterite/ampboil? composites were present in the panned non-magnetics concentrate with dominant pyrite as seen In **Table Eight.** Note that 96% of the Mozley middlings are magnetic. Results for both show that the high gradient magnetic separation carried out in Perth removed very little para magnetic material.

Magnetically separating the Mozley tail indicated that again over 90% of this product is magnetic, but when panning the non-magnetics, no upgrading was observed and it was abandoned. **Figure Six** indicates that just less than 50% of the cassiterite is free and if the mags from the Mozley tail were discharged to tailings, then 66% of the weight in this fraction would be rejected at 0.14% Sn and 21% of the tin in this fraction would be rejected.

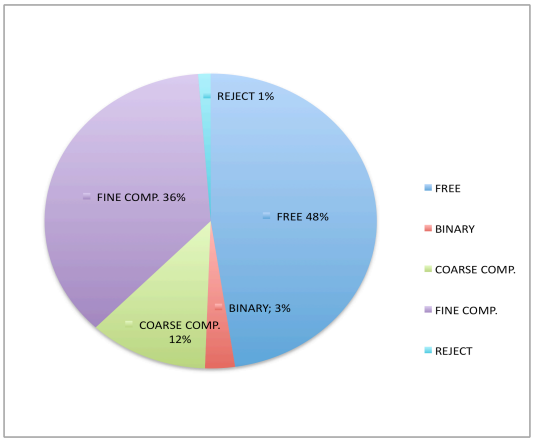
Figure Six
Tin Distribution 106µm



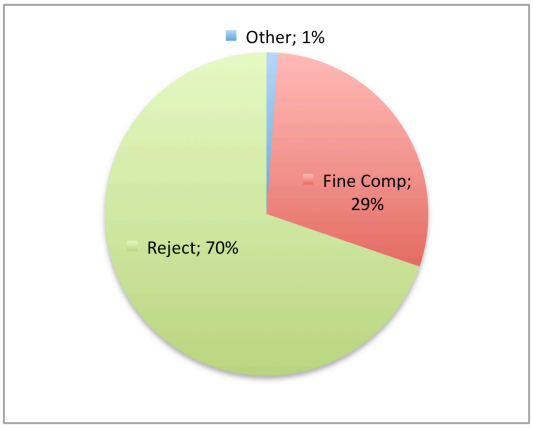


Figure Seven
Weight Rejection At 0.13%

Comments

An acceptable high-grade concentrate was not produced at 106µm, nor was the target tail achieved. Rejection of the Mozley tail after magnetic separation, combined with the panned tail (No.6) in **Table Eleven,** show that 70% of the weight can be rejected at 0.13% Sn as shown in **Table Seven**. **Figure Six** estimates the tin distribution, and shows little tin reporting as "binary" composites.

Assay			0.76	0.02	17.70	0.21				

Comments

The Mozley performed well and excellent upgrading was achieved at about 16:1 with moderate recovery as seen in **Table Eleven**. A large middlings was produced in an effort to obtain a throwaway tail assaying <0.10% Sn; again this was not achieved, even though maximum effort was involved in trying to obtain a low tail. Because of the difficulty observed in obtaining a "clean" high grade concentrate when panning the 106µm fraction it was decided to magnetically separate the Mozley concentrate to allow a high grade concentrate to be produced.

Comments

In **Table Twelve** the response of the Mozley concentrate to magnetic separation was significant. The non-magnetics assayed 36.7% Sn and this product was easily and very quickly upgraded to 59% Sn at very high recovery. An interesting observation of the panned concentrate was the fact that the WO3 assay was only 2.25%; observation under the UV light suggested at least 25% of the concentrate was scheelite. The magnetics were another matter altogether as 23% of the cassiterite reported to this product at 3% Sn, and when panned significant composite cassiterite reported to the concentrate, which assayed 33.7%Sn, and when combined with the non magnetics the combined concentrate assayed at about 55% Sn. When the mags concentrate was observed under the microscope a lot of the cassiterite had small dark/black specks attached to the cassiterite grain as well as the more obvious siderite/cassiterite composites? In addition about 52% of the tin reported to the panned middlings and the production a rejectable tail was not even close.

Comments

The Mozley middlings were magnetically separated and the non-mags panned. It is important to note that 63% of the tin in the middlings reported to the mags at 0.24% Sn as seen in **Table Thirteen**. Panning the non-mags produced a concentrate assaying 16.25% Sn. When observed under the microscope no free cassiterite was seen and all the cassiterite contained small dark/black specks attached to the cassiterite grain as well as the more dominant siderite/cassiterite composites. Sadly the tail did not reach the target of 0.10% Sn. When the panned concentrate was examined under the UV light the scheelite seemed to suggest much higher grades that the assay revealed.

Comments

When subjected to magnetic separation 89% of the mass reported to the mags fraction and the assays reveal that magnetic separation did not quite yield the target of< 0.10% Sn, but because of 65% of the weight in this fraction reports to the mags, it is an economic decision to regrind this product to allow a very small amount of tin to be recovered. Panning the non-mags yielded a rejectable tail. The panned concentrate contains very little identifiable cassiterite, but the scheelite could be readily identified under the UV light.

Comments

It is estimated that at 75µm about 58% of the cassiterite is free, just under 69 % of the weight at 0.11% Sn could be rejected, which is marginally above the cut off grade of<0.10% Sn. Some 23% of the tin reports to the “coarse “ middlings which should be recoverable with only a light grind. In

Figures Ten & Eleven below it can be said that the benefits of regrinding nearly all this fraction are costly and problematic as any cassiterite contained in the marginal tails will be very fine and the economics of regrinding are starkly portrayed. It would seem that the 75µm flow sheet is the most economical and practical for the gravity separation process for Mt. Lindsay. Cassiterite liberation estimation is given in **Figure Nine** and shows that liberation is not complete. If a target tailing of <0.10% Sn has to be reached then in practice all middlings and tails above 75µm should be reground to 100% passing 75µm. On the other hand if the lowest particle tailing is accepted, then 69% of the weight in this fraction can be rejected at 0.11% S.

Assay			1.04	0.01	17.00	0.19				

Comments

At 53µm it can be seen in **Table Sixteen** that at last liberation has occurred and rejectable tails can be produced and 52% of the weight can be rejected directly at acceptable tailings grade. This might even be reduced further by magnetic separation using the same flow as used for the 75µm fraction.

Comments

In **Table Seventeen** it can be seen that the Mozley concentrate was magnetically separated, tin recovery to the non-mags was good, panning produced an excellent concentrate at high recovery, and when examined under the microscope only free pyrite was observed, but again the sheelite was much lower than “observed” under the UV.

Panning the mags shows that about 8% of the tin has small magnetic inclusions, these were difficult to clearly identify under the stereo binocular microscope, but sulphides and siderite were common.

Overall tin recovery for the 53µm fraction was 92% and the concentrate grade was 59%. It is estimated that with a sulphide cleaning circuit installed on the final concentrate a >62% Sn can be obtained. In retrospect further processing the Mozley middlings and tails was warranted.

Comments

Overall gravity and magnetic separation performance at 53µm was satisfactory as shown in **Table Eighteen** and it is probable that "acceptable" recovery only occurs at this size. In comparison to Cleveland and Renison, equivalent liberation occurs at about 106µm. Tin recovery for the fraction was 82.4% to a 59.5 % concentrate. Scheelite and sulphide removal should lift grade to >64% Sn for very little loss and the binary cassiterite will not require further grinding. This is illustrated in **Figure Thirteen** and in total about 63% of the weight can be rejected.

Assay			1.19	0.01	16.40	0.16				

Comments

In order to compare the effect of magnetic separation on tin recovery the 38µm fraction was treated on the Mozley table and the Mozley concentrate was cleaned on the vanning plaque as shown in **Table Nineteen**. The Mozley performance was good, the ratio of enrichment was almost 15:1 and recovery was 91.4%. It is probable that even higher recoveries could be achieved because a very large middlings fraction was taken. There was a wide discrepancy between the calculated tin value and the assayed head.

Table Twenty
38µm Mozley Concentrate Cleaning

>38µm Mozley Conc										
			Assays				Disribution			
Panning	Wt	Wt %	Sn%	WO3%	Fe%	S%	Sn%	WO3%	Fe%	S%
>38µm Panned Conc	2.90	33.86	57.3	0.36	8.2	1.9	91.5	76.6	17.4	37.8

			21.18	0.15	15.4	1.64				

Comments

Cleaning recovery was high, but the concentrate grade was low as seen in **Table Twenty.** Microscopic examination notes indicated that pyrite, siderite and scheelite content were low, and no composites were detected. At this size detailed examination with the stereomicroscope is difficult.

Comments

An overall tin recovery was only fair at 84.5% into a 57.3% as shown in **Table Twenty One** which is just slightly better than the 53µm performance. At 38µm a 65% Sn concentrate should be readily produced and recovery should be at least 90%. The conclusion that can be drawn from comparing the 75µm, 53µm and 38µm fine fractions is that magnetically separating the gravity tails will produce a throwaway tail and it is necessary to also magnetically separate the gravity concentrate. This may best be done in a final tin treatment (FTT) circuit where electrostatic separation (>75µm only) sulphide removal and magnetic separation would take place. In **Figure Sevneteen** it is estimated that 84% of the tin occurs as free cassiterite and 6% as “binary composites. In **Figure Sixteen** it can be seen that the fine composite weight distribution is very large.

Comments

This fraction (CS1) taken from the cyclosizer is an artifical product produced from the preferential process that occurs in the cyclosizer, this is clearly seen in **Table Twenty Two**. The CS1 product is always high grade and contains a disproportional distribution of heavy minerals. Because of the small weight and high grade, this fraction was treated directly on the vanning plaque.

Figure Eighteen

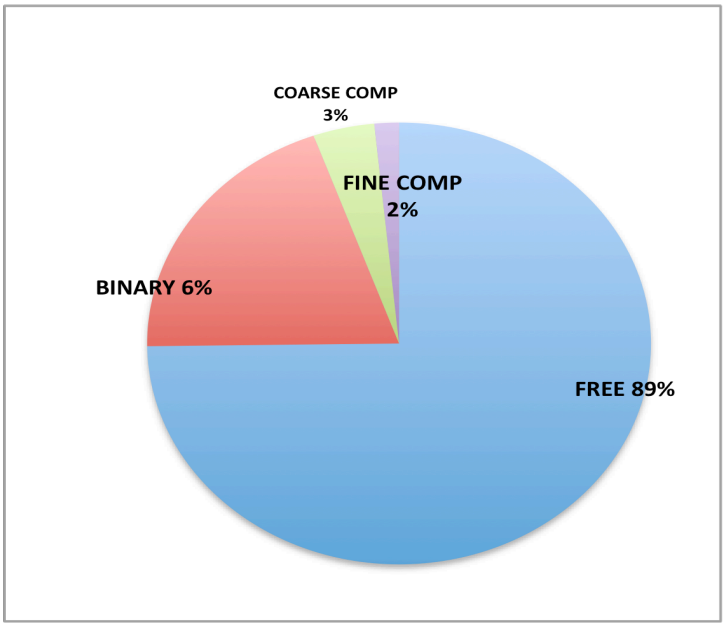
	Assay		7.55	0.05	15.4	0.58					



Comments

Overall recovery was very high at 95.2% for the 26µm fraction and combined concentrate assayed 54%Sn and 2%S. The high-grade concentrate grade was much lower than expected as seen in **Table Twenty Three**. Only what was considered cassiterite was collected in this "very" high-grade concentrate and cursory examination under the microscope supported this observation.

This supports the evidence from previous tests that obtaining a final high grade concentrate without magnetic separation is very difficult on Mt. Lindsay ore.

Magnetic separation is a vexed issue for this ore body as about 20% of the cassiterite in this fraction was recovered from the magnetics at just under 40% Sn. **Figure Nineteen** illustrates the problem of what can be considered "free"; the panned concentrate from the mags will assay just under 50% Sn if all the sulphides are removed.

Comments

Table Twenty Four shows that neither gravity separation nor dry magnetic separation work well at this size, so results are only indicative as all minerals should be free and only 58.4% of the tin was recovered.

Comments

It is worth commenting on the metal distribution in the fines in **Table Twenty Five.** As in previous investigations, tin distribution in the <5µm fraction is very low compared to the other elements. Note that only 3.7% of the tin reports in this fraction, but just under 25% of the tungsten reports here. It is one of the tungsten oxide minerals.

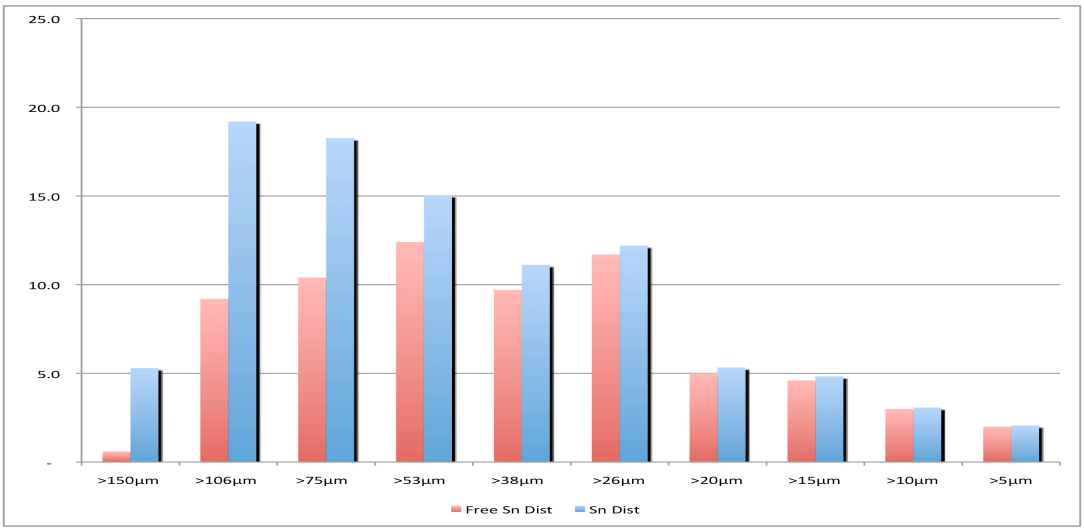
3 – Data Evaluation And Comparison

3.1 – Tin Liberation

Overall Performance

Figure Twenty One shows tin cassiterite liberation on a size-by-size basis and this indicates a typical liberation profile and overall 63.2% of the tin was recovered into a low grade concentrate assaying 43.5% Sn. In addition, 57.15% of the tin was recovered into a "high" grade concentrate assaying 48.0% Sn. If Stokes Law is applied then only 48% of the tin was recovered into a 41.8% concentrate in the recoverable >38µm. It can be estimated that if a 65% Sn gravity concentrate is desirable, recovery will drop to about 40% on these figures.

Figure Twenty One
Mt. Lindsay Free Tin Distribution



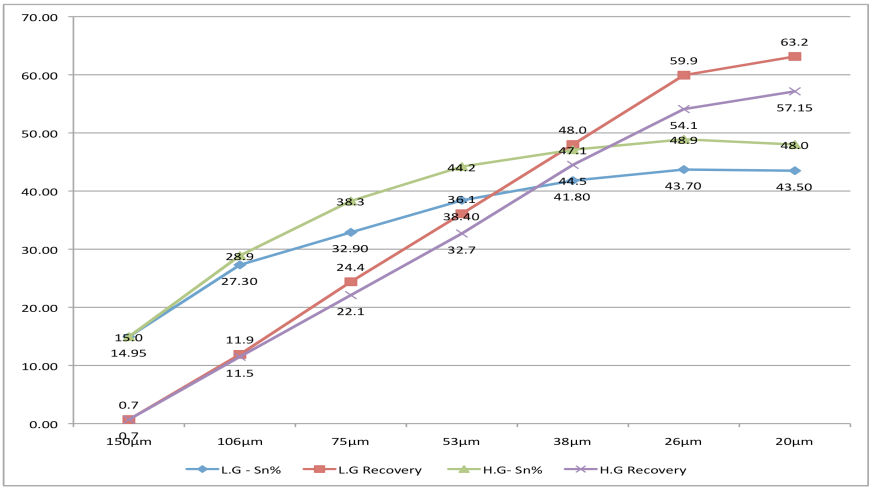


Figure Twenty Two
Mt. Lindsay Grade Recovery Curve (size X size)

3.2 – Mt Lindsay Comparison

Figure Twenty Three, which compares Mt. Lindsay cassiterite to other ore bodies, gives much comfort when compared to difficult ore bodies such as Gillian and Queen Hill. It can be seen that liberation at 150µm for Mt. Lindsay is very low, but once Mt Lindsay reaches 38µm it has the highest liberation profile of any of the ore types compared The Sligo deposit at Renison has the closest liberation profile. It can be readily seen that while Mt. Lindsay cassiterite is a lot finer than Cleveland it is not anything like as difficult as Gillian or Queen Hill. The only thing is that the emphasis on flotation is a lot greater than Cleveland, Ardlethan or Renson where flotation added another 7% to 12% to overall tin recovery. At Mt Lindsay it now seems that 35% of the tin will be recovered by gravity, another 37% will be recovered by flotation and this is most important as Venture will need to achieve both grade and recovery from flotation. In the 2009 investigation the search for grade was pursued more vigorously and therefore recovery is lower as shown in **Table Twenty Three**. **Table Twenty Four** (November 2011) recovery was pursued and reported a 42% tin recovery into a 20% Sn concentrate. In some of the earlier investigations more cassiterite was liberated before the 150µm fraction. In a 2009 report the tin liberated at 210µm, meaning that there is a variability in the cassiterite grain size at Mt Lindsay as shown below In **Figure Twenty Five.** The work carried out in late 2011 compares to this work very closely. The possibility of using C and UF Falcons also needs to be investigated because so much of the cassiterite lies in the <38µm and >5µm and these fractions are readily recoverable in the Falcon centrifuges when they are set up correctly.

3.3 – Discussion on Flow Sheet

The reasoning for using magnetic separation in different ways can be seen below in **Figure Twenty Six** and **Table Twenty Four.** The flow sheet is self-explanatory and alternative strategies were tried. No magnetic separation at 150µm.

On the 106µm fraction, both the Mozley middlings and tails were magnetically separated to see if tin recovery could be improved and this was readily demonstrated. It was attempted to recover a saleable grade concentrate directly without magnetic separation but this proved difficult. All Mozley fractions from the 75µm fraction were magnetically separated before gravity separation and so on down to 20µm. In **Figure Twenty Six** the full flow sheet used for this investigation is shown.

3.4 – Survey Comparison

Given below in **Tables Twenty Seven** and **Twenty Six** it can be seen that the distribution of tin and tungsten are similar in both surveys and this is reassuring as tin recovery was also close.

Comments

While the tin grade was lower in 2011, both the tin and tungsten distributions are very close except for the 26µm fraction distribution and that can be a function of the cyclosizer operation.

Conclusions

- This report involved a program of gravity and high gradient magnetic separation as well as stereomicroscopic examinations of selected products. The investigation was carried out on tailings taken on a whole ore flotation test for scheelite (WOFT) from a blended sample of Mt. Lindsay's two major primary ore types. The object was to establish the liberation characteristics for cassiterite and to identify potential processing routes for recovering tin. In this investigation soluble tin content was not assayed because of the problems ALS were having in setting up a new assaying service that was reliable and timely at their Burnie laboratory. The program of work established the following:

  - The high gradient magnetic separation test work carried out on this sample in Perth did not work very well as up to 88% of the material is magnetic at 8,500 gauss.

  - This report confirms the fact that the cassiterite at Mt. Lindsay is fine and over 90% lies within the recoverable range between 5µm and 150µm.

  - In this ore body the cassiterite does not slime which means that the tin loss in any de-sliming operation before cassiterite flotation will be low.

  - There is a slight variability in grain size, the coarser ore tested in 2009 starts liberating at 210µm and the finer ores tested in 2011 and 2012 liberate at 150µm.

  - On a primary grind of 80% passing 120µm the cassiterite liberation at different sizes is shown below:

    - At 150µm <10.0%
    - At 106µm 48%
    - At 75µm 64%
    - At 53µm 82%
    - At38µm 85%
    - At 26µm >95%
    - Overall liberation ≈ 72%

  Because significant cassiterite liberation does not start until the ore is ground to 80% passing 120µm and then complete liberation is only gradually reached, it very likely that on this sample of ore conventional gravity separation will only recover 30% to 40% of the cassiterite into a high grade gravity concentrate assaying >60% Sn.

  - It is difficult to achieve acceptable concentrate grades of >60% Sn without the help of magnetic separation.

  - It was found that at least 15% to 20% of the cassiterite has magnetic inclusions, but this cassiterire can be recovered into a gravity concentrate assaying between 35% and 40% Sn.

- Magnetic separation used directly on WOFT before gravity separation will incur significant tin losses as high as 25% on coarser fractions.

- In this investigation a reject tailing grade of <0.10% Sn was aimed for and achieving this grade did not occur until the 53µm fraction was reached.

- Nevertheless magnetic separation carried out on a gravity tails allow for at least 50% of the weight in the WOFT to be rejected at acceptable tailings grades of < 0.14% Sn in >38µm fractions.

- Rejection of tailings at grades of 0.14% Sn then becomes an economic decision and must involve an investigation into what tin recovery can be expected from what must be very fine particles of composite cassiterite in the >53µm tails.

- Alternatively If all gravity tailings are reground to 80% passing 45µm then using magnetic separation before cassiterite flotation should be beneficial in several ways.

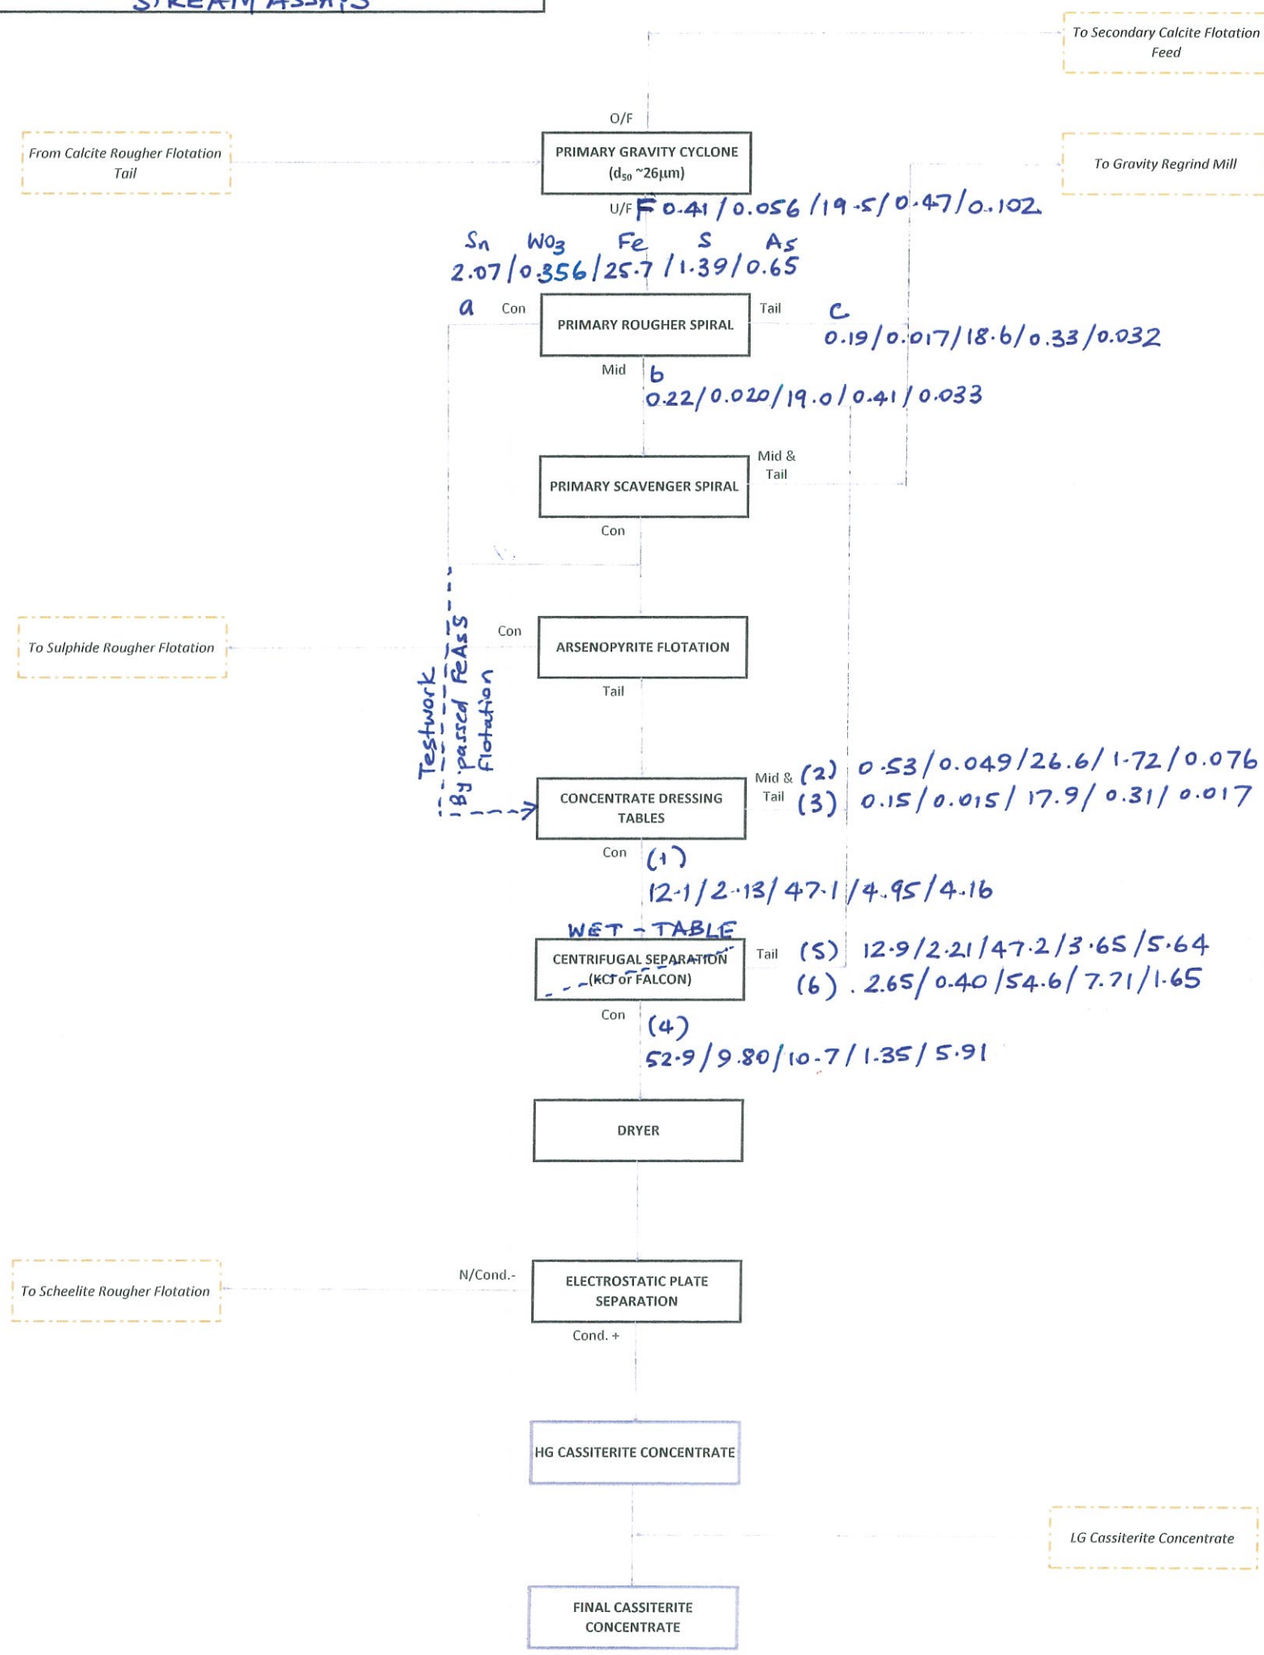
- A small amount of coarser free scheelite reported to WOFT and only assayed 0.03% WO3, this scheelite is readily recoverable by gravity separation and can be separated from the cassiterite by electro static separation as the scheelite is mostly coarser than 75µm.

- It is also interesting to note that even a small amount of scheelite in a panned concentrate can be easily over estimated if UV light is used to judge the scheelite content.

- Other common heavy minerals indentified include, magnetite, scheelite, pyrite, pyrrhotite, siderite and various amboils.

Recommendations

Investigate the recoverability of the fine composite cassiterite in gravity tails magnetics on the >53µm fractions as this report shows that it is possible to reject at least 70% of the weigh in the >53µm fractions at about <0.14% Sn.



Alternatively weigh up the advantages of regrinding all gravity tails and middlings to 80% passing 45µm and then removing 80% of the weight before tin flotation with high gradient magnetic separation.

Consider how best to clean a spiral concentrate in a final tin dressing circuit to maximise recovery and ensure the highest possible concentrate. The following processes will be involved:

- Sulphide Flotation.
- Table dressing
- Electrostatic separation on the >53µm fractions
- High Gradient magnetic separation.
- Modest regrinding of the middlings in a cracker mill.

The use of centrifuges such as Falcons needs to be investigated as this could have a significant improvement on the recovery of fine cassiterite.

1 INTRODUCTION

JKDrop-Weight & SMC data for sixteen samples from Venture Minerals were received from ALS Ammtec SA on July 19, 2012, by JKTech for JKDrop-Weight & SMC test analysis. The samples were identified as Main A, Main B, No. 2 A, No. 2 B, Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6. The data were analysed to determine the JKSimMet comminution parameters. SMC test results were forwarded to SMC Testing Pty Ltd for the analysis. The samples had been subjected to JKDrop-Weight testing (Main A, Main B, No. 2 A & No. 2 B) & SMC testing (Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6). Analysis and reporting were completed on July 24, 2012.

2 THE JK DROP-WEIGHT TEST

2.1 INTRODUCTION

The JKTech Drop-Weight test provides ore specific parameters for use in the JKSimMet Mineral Processing Simulator software. In JKSimMet, these parameters are combined with equipment details and operating conditions to analyse and/or predict SAG/autogenous mill performance. The same test procedure also provides ore type characterisation for the JKSimMet crusher model. These ore specific parameters have been calculated from the test results and are supplied to Venture Minerals Limited in this report as part of the standard procedure.

2.2 DROP-WEIGHT TEST PROCEDURE

Details of the JK Drop-Weight test procedure can be found in APPENDIX A.

2.3 INTERPRETATION OF DW TEST RESULTS

2.3.1 Resistance to Impact Breakage

One of the problems with the functional form used to represent the t_{10} v E_{cs} relationship is that the parameters A and b are not independent and thus cannot be used directly for comparisons between ore types. Two alternative parameters give a better comparison. These are the product A*b and the t_{10} achieved by the application of 1.0 kWh/t of Specific Comminution Energy (E_{cs}). For both of these parameters, a smaller number means a greater resistance to impact breakage.

2.3.2 Resistance to Abrasion Breakage

Resistance to abrasion is indicated by the t_a parameter. As with parameter A*b, a smaller value of t_a indicates more resistance, this time to abrasion breakage.

2.3.3 Effect of Particle Size on Resistance to Impact Breakage

Variation of impact resistance with particle size is important for crusher power draw calculations and SAG/autogenous mill media competency considerations. Some ores exhibit a significant decrease in impact resistance with increasing particle size while others show no variation with size. The opposite trend of increasing impact resistance with increasing particle size is extremely rare.

The trend most frequently observed is for there to be decreasing slope with decreasing energy (E_{cs} values). However, it is both the slope and the absolute values of the low energy t_{10} values that are of interest for SAG/autogenous milling because these data give an indication of the ability of media particles to survive. If the trend of the t_{10} values with increasing particle size is significantly upwards, it can be inferred by extrapolation that particles in the 100 – 200 mm size range (normal media size) will not be strong enough to survive. The same argument applies if the absolute values of t_{10} at low energy are sufficiently high.

2.3.4 Density Results

As part of the standard JKTech ore property assessment procedures, the relative density of 30 randomly selected particles in the size range 26.5 mm to 31.5 mm are determined by weighing each particle, suspended initially in air and then in water.

It should be noted that this method measures the density of the particle rather than the density of the solid phase, since any internal porosity will be included in the volume measurement. A more accurate measurement of the solid phase density is possible using a Helium Pycnometer. However, it is the particle density rather than the phase density that is of concern in the assessment of SAG milling properties.

Even at the coarse particle sizes tested, it is normal to find a range of relative densities as the mineralogy of the particles varies. However, of great concern in SAG/autogenous milling is the possibility of a component in the ore that is both high density and resistant to breakage. Such material will concentrate in the load in a SAG/autogenous mill and result in higher than expected power draw.

2.4 DW TEST RESULTS

2.4.1 Summary of SAG/autogenous Mill Model Parameters

Table 1 shows the SAG/autogenous mill model parameters for Main A, Main B, No. 2 A & No. 2 B.

Table 1 - SAG/Autogenous Mill Parameters from DW Test Results

Ore Type	A	b	A * b	t_a
Main A	55.70	0.56	31.2	0.34
Main B	65.30	0.48	31.3	0.38
No. 2 A	64.00	0.63	40.3	0.28
No. 2 B	68.10	0.59	40.2	0.33

The frequency distribution of the parameters A*b and t_{10}@1kWh/t from the JKTech database of ores tested are given in Figure 1 and Figure 2 respectively.

The A*b values and the t_{10} at 1 kWh/t are given for the samples Main A, Main B, No. 2 A & No. 2 B in Table 2, which also includes figures from the JKTech database of ores tested for comparison.

Table 2 – Parameters Compared with Population of Values from Database

Ore Type	A * b			t10 @ Ecs = 1kWh/t			t_a		
	Value	Rank	%	Value	Rank	%	Value	Rank	%
Data Base Min (hardest)	12.9	1	0	7.9	1	0	0.0	1	0
Data Base Median	47.2	1,914	50	32.5	1,913	50	0.5	2,017	50
Data Base Mean	64.8	2,735	71.5	34.9	2,246	58.7	0.6	2,709	69.1
Data Base Max (softest)	809.6	3,825	100	93.6	3,825	100	6.9	3,918	100
Main A	31.2	626	16.4	23.9	547	14.3	0.34	1,103	28.2
Main B	31.3	637	16.7	24.9	669	17.5	0.38	1,430	36.5
No. 2 A	40.3	1,422	37.2	29.9	1,520	39.7	0.28	684	17.5
No. 2 B	40.2	1,403	36.7	30.4	1,591	41.6	0.33	1,038	26.5

The frequency distribution of the t_a parameter from the JKTech database of ores tested is given in Figure 3.

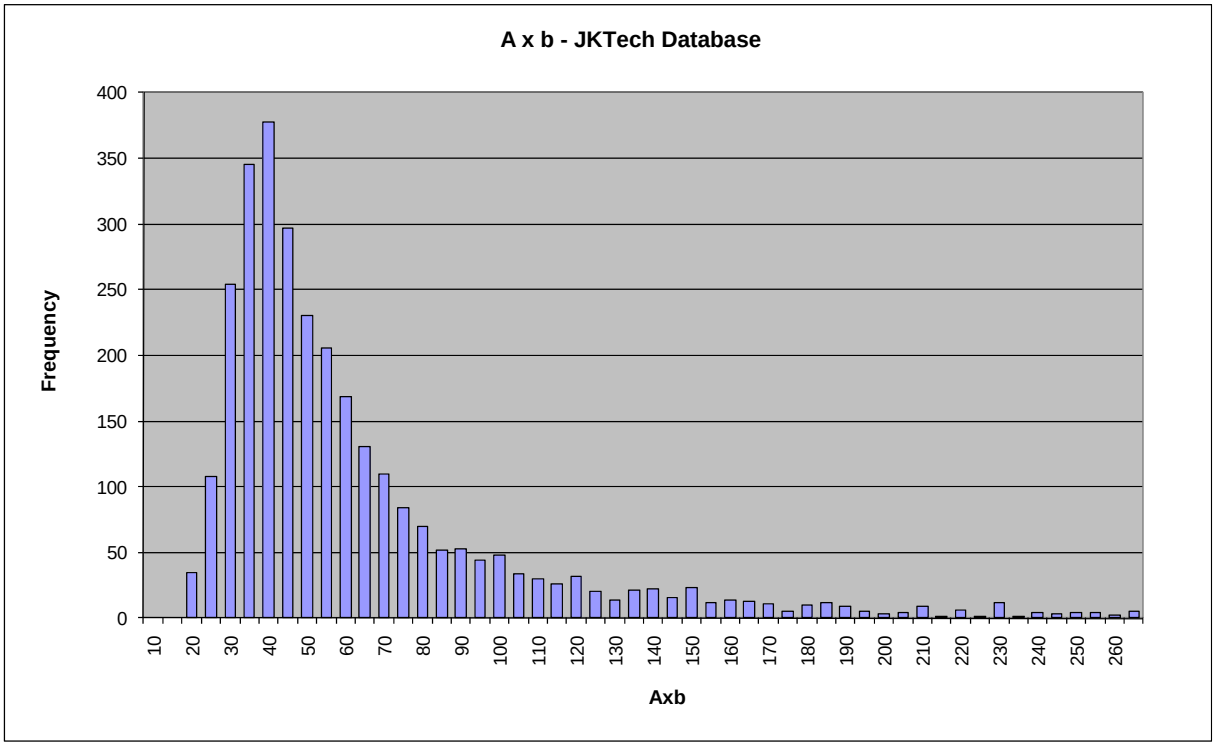

Figure 1 - Frequency Distribution of A*b in the JKTech Database

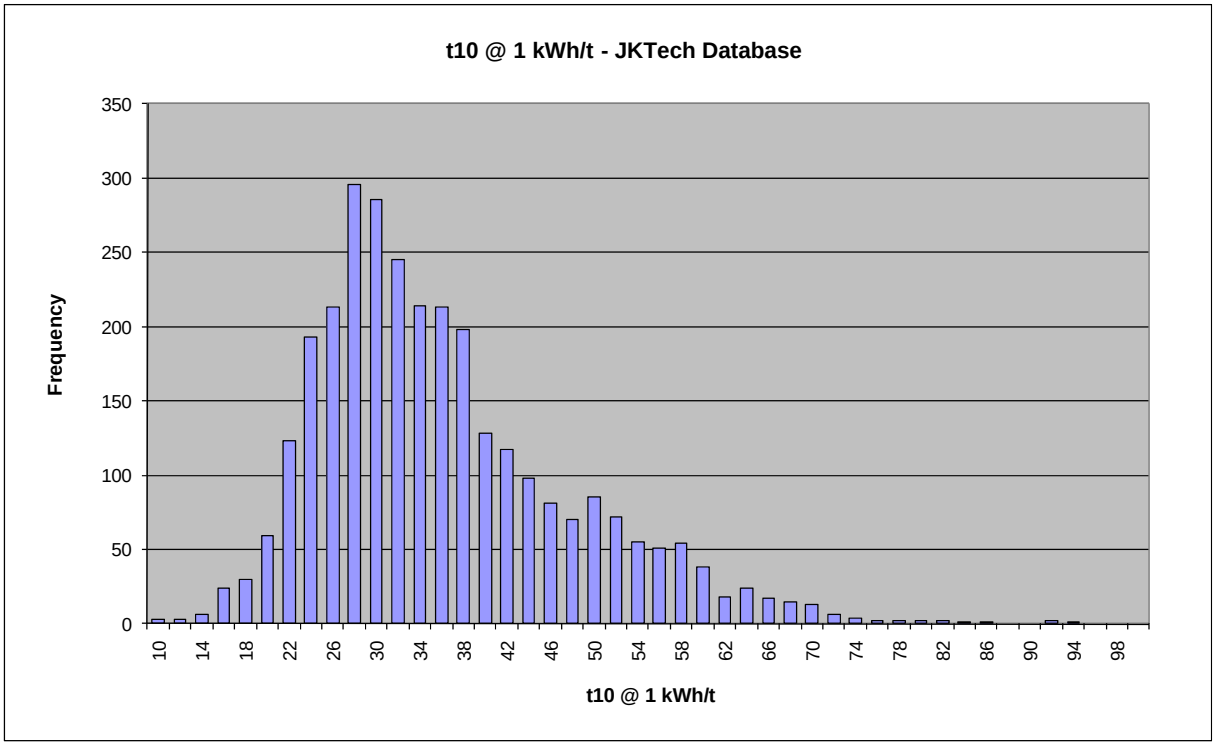

Figure 2 - Frequency Distribution of t_{10}@1kWh/t in the JKTech Database

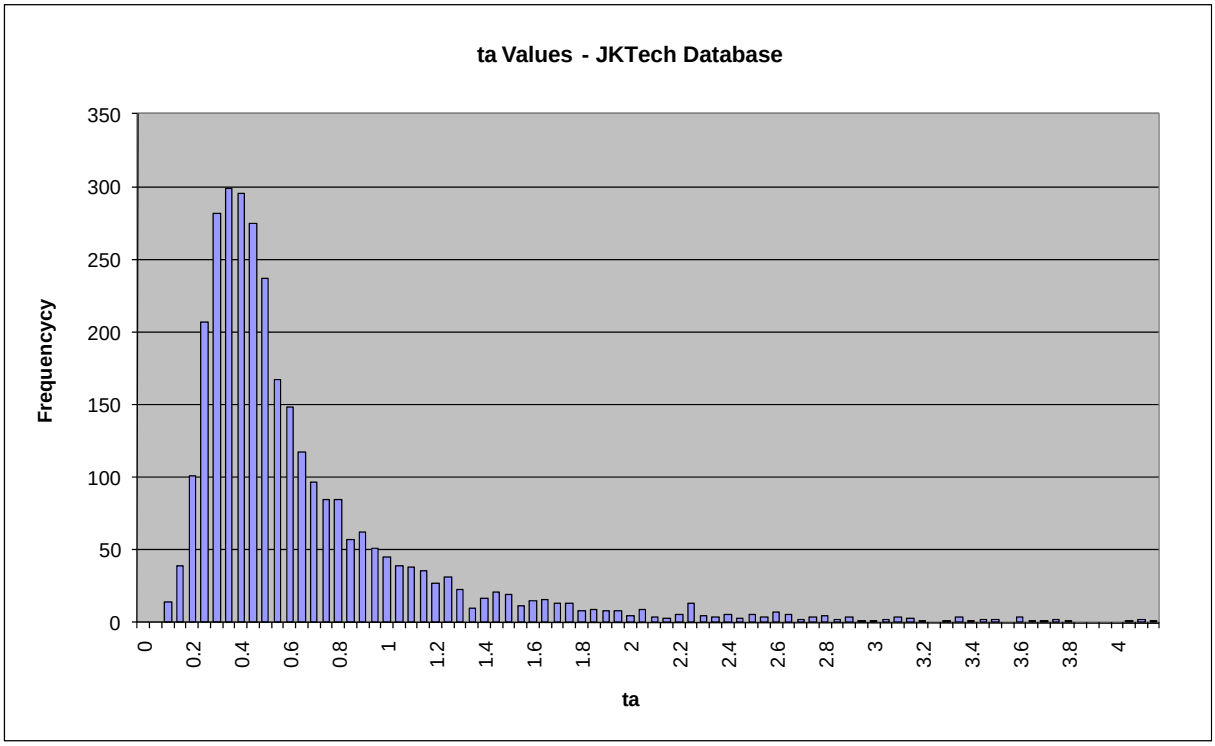

Figure 3 - Frequency Distribution of t_a in the JKTech Database

2.4.2 DW Test Results for Main A

The t_{10} versus E_{cs} relationship for sample Main A is given in Figure 4.

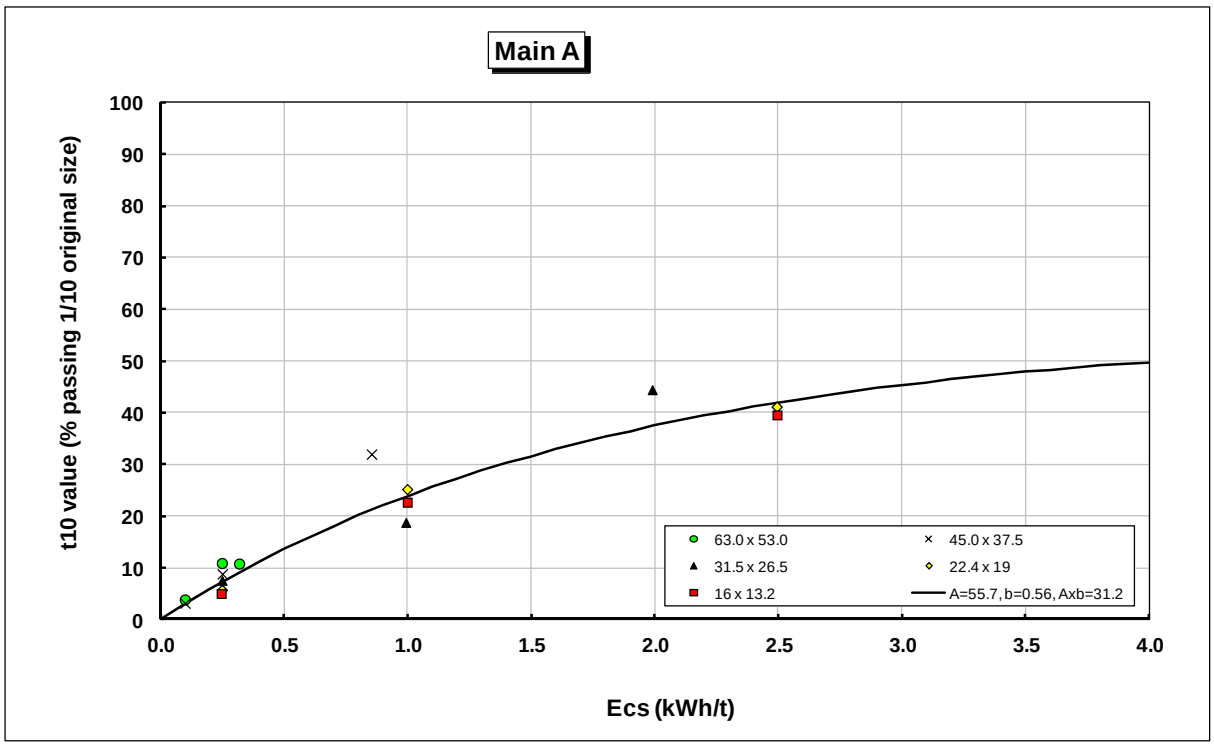

Figure 4 – t_{10}/ E_{cs} Relationships for Main A

Main A has an A*b value of 31.2, which puts this material in the hard range of resistance to impact breakage. In the JKTech database, 16.4% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.34, Main A falls into the hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 28.2% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample Main A are given in Table 3 below.

The data in Table 3 indicate that for particles of Main A of up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 3 - Crusher Model Parameters for Main A

	Size Relative to Initial Size				
	t75	**t50**	**t25**	**t4**	**t2**
t10	**cumulative percent passing**				
10.0	2.70	3.30	5.05	24.23	56.18
20.0	5.63	6.84	10.33	47.07	87.73
30.0	8.78	10.65	15.65	66.45	100.00

Specific Comminution Energy:

	Initial Particle Size, mm				
	+13.2-16.0 14.53	**+19.0-22.4 20.63**	**+26.5-31.5 28.89**	**+37.5-45.0 41.08**	**+53.0-63.0 57.78**
t_{10}	**E_{cs}, kWh/t**				
10	0.43	0.43	0.41	0.26	~~0.26~~
20	0.95	0.91	0.86	0.54	~~0.54~~
30	1.60	1.43	1.38	0.87	~~0.87~~

The Ecs values for 20.63 mm particles at t10 = 10 and 20 have been modified to avoid unrealistic extrapolation of energy requirements at lower sizes. The Ecs values for 57.78 mm particles at t10 = 10, 20 and 30 are doubtful. Values from the next finest particle size have been substituted.

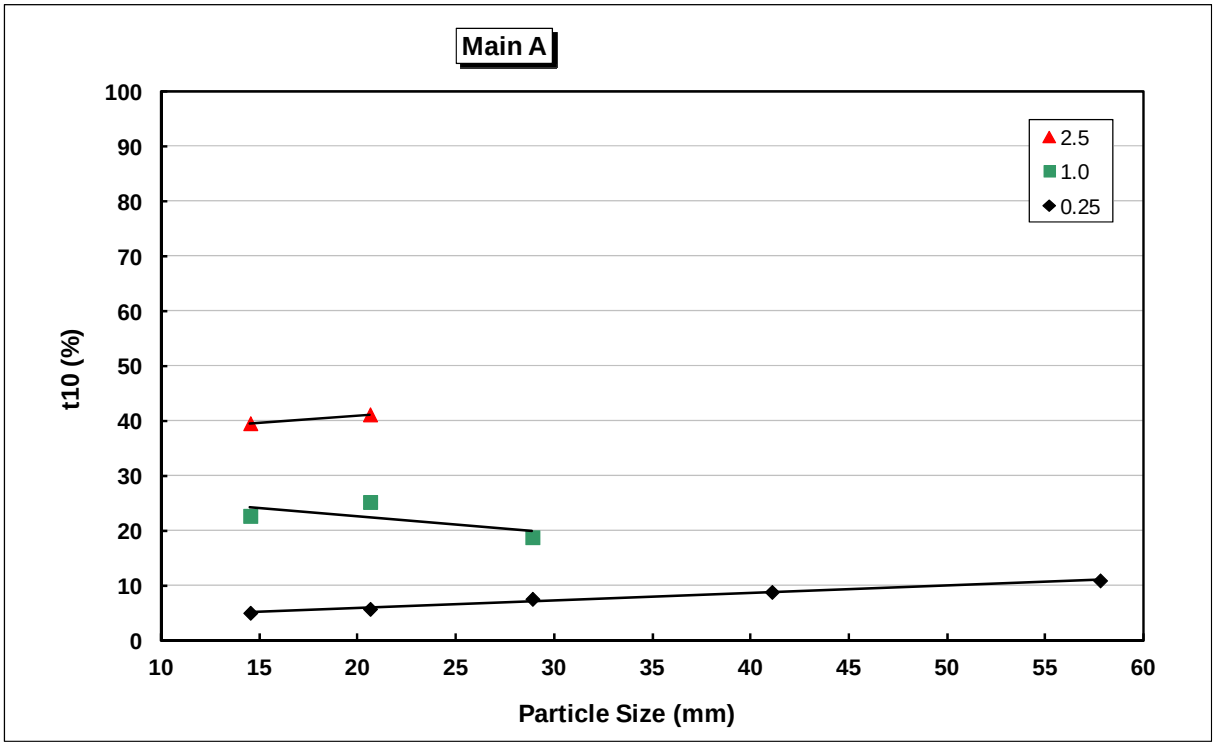

Figure 5 - Variation of Impact Resistance with Particle Size - Main A

The data graphed in Figure 5 are the t_{10} values for up to 5 different particle sizes from Main A, all broken with the very similar specific comminution energies (0.25 kWh/t, 1.0 kWh/t and 2.5 kWh/t).

The data for Main A do not follow the frequently observed trend of decreasing slope with decreasing energy (E_{cs} values).

The density measurements for the 30 particles from Main A are given in Table 4 below. These results are plotted as a histogram in Figure 6.

Table 4 - Relative Density Measurements for 30 Particles for Main A

3.45	3.57	3.27	3.28	3.67
3.35	3.38	3.38	3.42	3.60
3.35	3.67	3.81	3.51	3.75
4.10	3.55	3.43	3.50	3.27
3.29	4.19	3.42	3.32	3.61
3.38	3.36	3.49	3.68	3.93
Mean				**3.53**
Standard Deviation				**0.24**
Maximum				**4.19**
Minimum				**3.27**

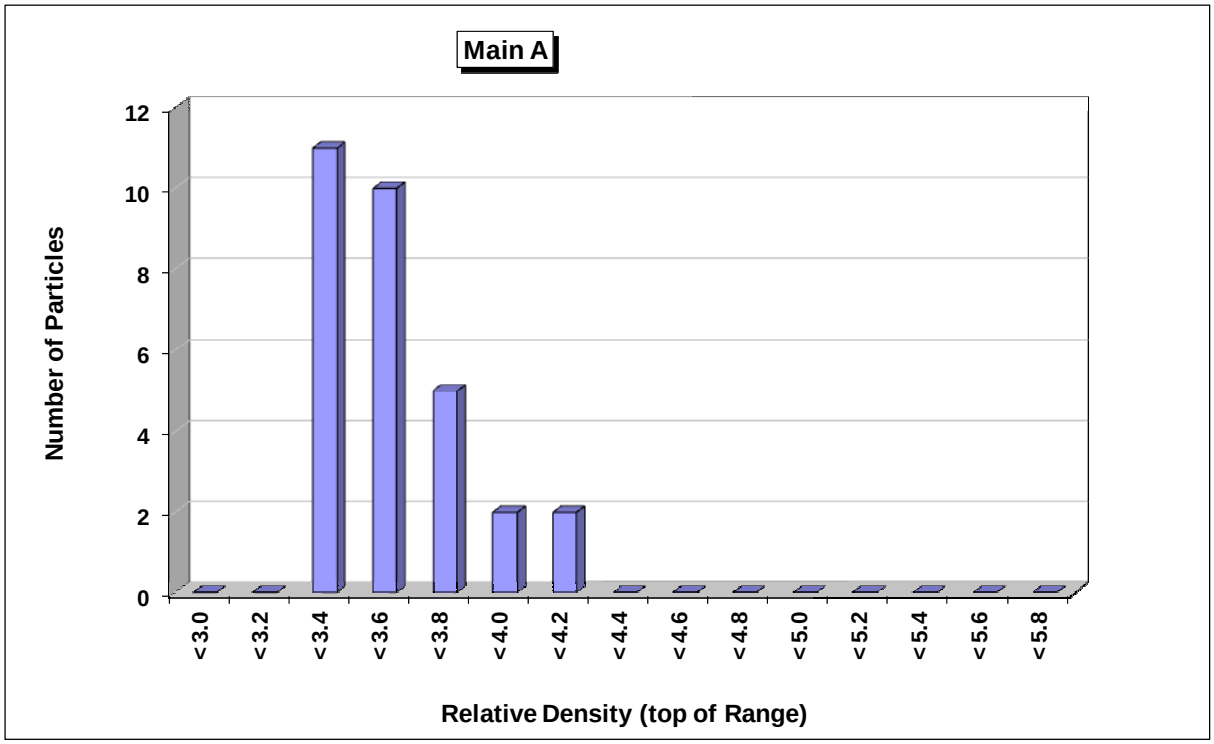

Figure 6 - Histogram of the Relative Density Measurements for 30 Particles for Main A

The Main A data contain definite evidence of bimodality in the relative density distribution, that is, definite evidence of a dense component that could concentrate in the mill load and cause power problems, resulting in a loss of throughput.

2.4.3 DW Test Results for Main B

The t_{10} versus E_{cs} relationship for sample Main B is given in Figure 7.

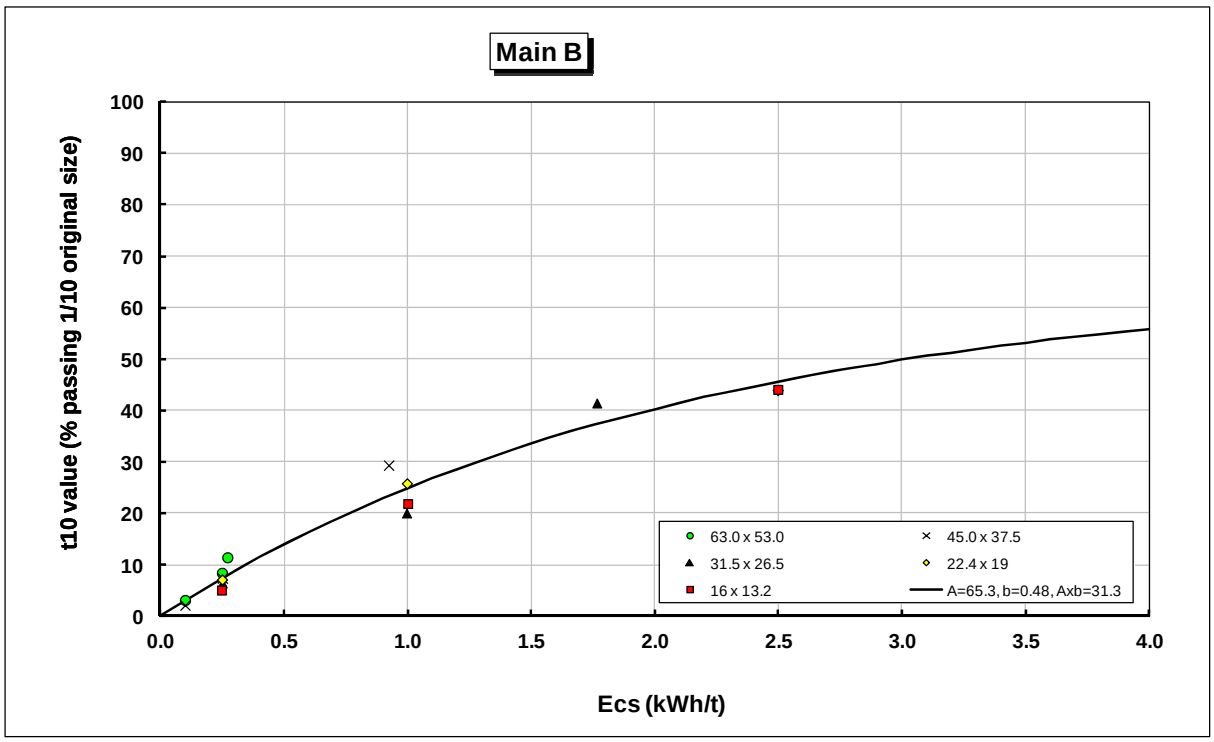

Figure 7 – t_{10}/ E_{cs} Relationships for Main B

Main B has an A*b value of 31.3, which puts this material in the hard range of resistance to impact breakage. In the JKTech database, 16.7% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.38, Main B falls into the moderately hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 36.5% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample Main B are given in Table 5 below.

The data in Table 5 indicate that for particles of Main B up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 5 - Crusher Model Parameters for Main B

	Size Relative to Initial Size				
	t_{75}	t_{50}	t_{25}	t_4	t_2

The Main B data contain definite evidence of bimodality in the relative density distribution, that is, definite evidence of a dense component that could concentrate in the mill load and cause power problems, resulting in a loss of throughput.

2.4.4 DW Test Results for No. 2 A

The t_{10} versus E_{cs} relationship for sample No. 2 A is given in Figure 10.

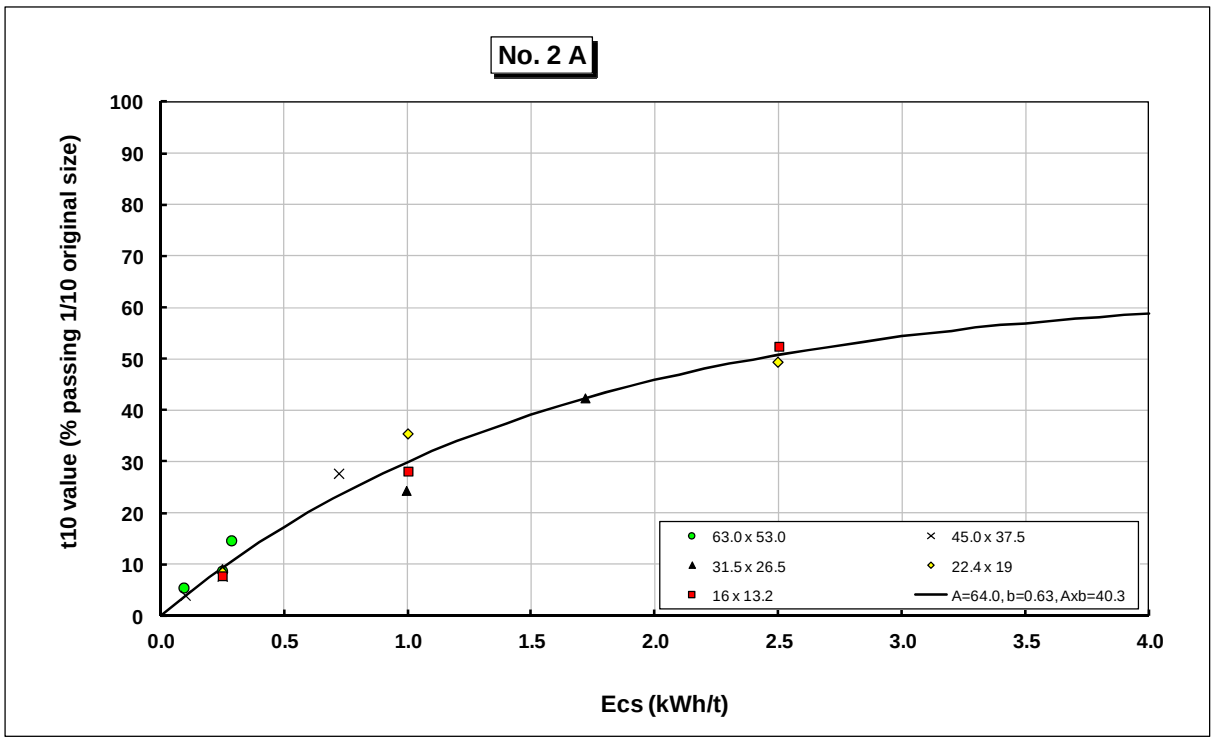

Figure 10 – t_{10}/ E_{cs} Relationships for No. 2 A

No. 2 A has an A*b value of 40.3, which puts this material in the moderately hard range of resistance to impact breakage. In the JKTech database, 37.2% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.28, No. 2 A falls into the hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 17.5% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample No. 2 A are given in Table 7 below.

The data in Table 7 indicate that for particles of No. 2 A up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 7 - Crusher Model Parameters for No. 2 A

	Size Relative to Initial Size				
	t_{75}	t_{50}	t_{25}	t_4	t_2
t_{10}	cumulative percent passing

3 THE SMC TEST®

3.1 INTRODUCTION

The standard JK Drop-Weight test provides ore specific parameters for use in the JKSimMet Mineral Processing Simulator software. In JKSimMet, these parameters are combined with equipment details and operating conditions to analyse and/or predict SAG/autogenous mill performance. The same test procedure also provides ore type characterisation for the JKSimMet crusher model.

The SMC (SAG Mill Comminution) test was developed by Steve Morrell of SMC Testing Pty Ltd (SMCT) to provide a cost effective means of obtaining these parameters from drill core or in situations where limited quantities of material are available. The ore specific parameters have been calculated from the test results and are supplied to Venture Minerals Limited in this report as part of the standard procedure

3.2 GENERAL DESCRIPTION AND TEST BACKGROUND

The SMC Test® was originally designed for the breakage characterisation of drill core and it generates a relationship between input energy (kWh/t) and the percent of broken product passing a specified sieve size. The results are used to determine the so-called JK Drop-Weight index (DWi), which is a measure of the strength of the rock when broken under impact conditions and has the units kWh/m^3. The DWi is directly related to the JK rock breakage parameters A and b and hence can be used to estimate the values of these parameters as well as being correlated with the JK abrasion parameter - t_a. For crusher modelling the t_{10}-E_{cs} matrix can also be derived. This is done by using the size-by-size A*b values that are used in the SMC Test® data analysis (see below) to estimate the t_{10}-E_{cs} values for each of the relevant size fractions in the crusher model matrix.

For power-based calculations, (see APPENDIX C), the SMC Test® provides the comminution parameters M_{ia}, M_{ih} and M_{ic}. M_{ia} is the work index for the grinding of coarser particles (> 750 µm) in tumbling mills such as autogenous (AG), semi-autogenous (SAG), rod and ball mills. M_{ih} is the work index for the grinding in High Pressure Grinding Rolls (HPGR) and M_{ic} for size reduction in conventional crushers.

The SMC Test® is a precision test, which uses particles that are either cut from drill core using a diamond saw to achieve close size replication or else selected from crushed material so that particle mass variation is controlled within a prescribed range. The particles are then broken at a number of prescribed impact energies. The high degree of control imposed on both the size of particles and the breakage energies used, means that the test is largely free of the repeatability problems associated with tumbling-mill based tests. Such tests usually suffer from variations in feed size (which is not closely controlled) and energy input, often assumed to be constant when in reality it can be highly variable (Levin, 1989).

The relationship between the DWi and the JK rock breakage parameters makes use of the size-by-size nature of rock strength that is often apparent from the results of full JK Drop-Weight tests. The effect is illustrated in Figure 16, which plots the normalized values of A*b against particle size. This figure also shows how the gradient of these plots varies across the full range of rock types tested. In the case

of a conventional JK Drop-Weight test, these values are effectively averaged and a mean value of A and b is reported. The SMC Test® uses a single size and makes use of relationships such as that shown in Figure 16 to predict the A and b of the particle size that has the same value as the mean for a JK full Drop-Weight test.

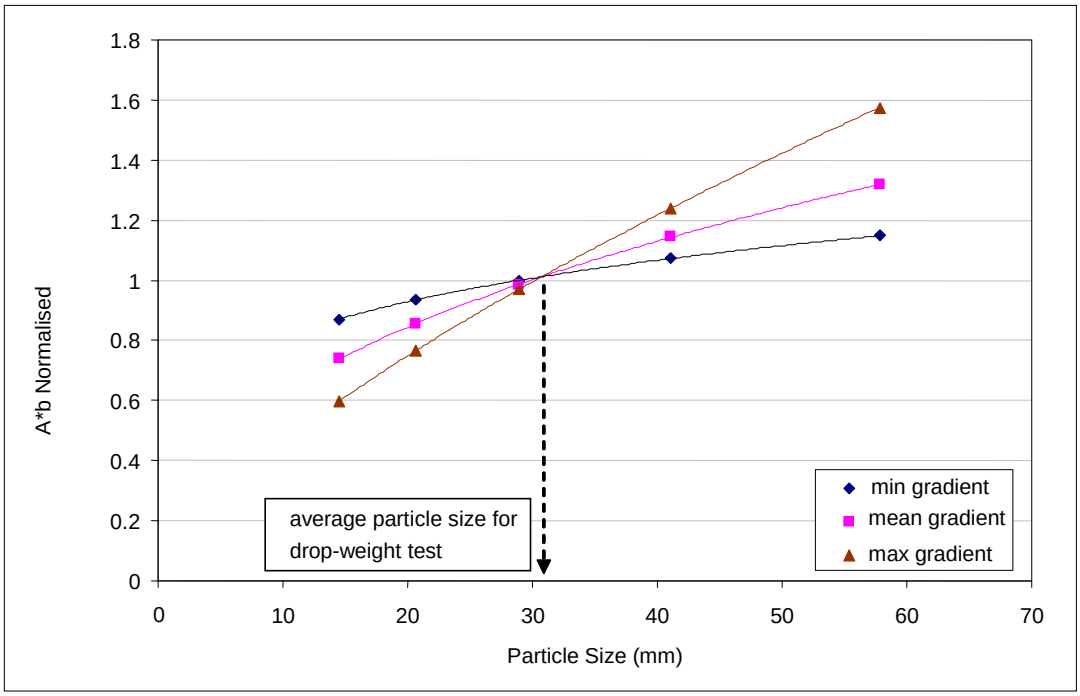

Figure 16 – Relationship between Particle Size and A*b

3.3 THE TEST PROCEDURE

In the SMC Test®, five sets of 20 particles are broken, each set at a different specific energy level, using a JK Drop-Weight tester. The breakage products are screened at a sieve size selected to provide a direct measurement of the t_{10} value.

The test calls for a prescribed target average volume for the particles, with the target being chosen to be equivalent to the mean volume of particles in one of the standard JK Drop-Weight test size fractions.

The rest height of the drop-head (gap) is recorded after breakage of each particle to allow for a correction to the drop energy. After breaking all 20 particles in a set, the broken product is sieved at an aperture size, one tenth of the original particle size. Thus, the percent passing mass gives a direct reading of the t_{10} value for breakage at that energy level.

There are two alternative methods of preparing the particle sets for breakage testing: the particle selection method and the cut core method. The particle selection method is the most commonly used as it is generally less time consuming. The cut core method requires less material, so tends to be used as a fallback method, only when necessary to cope with restricted sample availability.

3.3.1 Particle Selection Method

For the particle selection method, the test is carried out on material in one of three alternative size fractions: -31.5+26.5, -22.4+19 or -16+13.2 mm. The largest size

fraction is preferred but requires more material. The middle size fraction tends to be most commonly used, whilst the finest size fraction tends only to be used if there is an issue with starting material size distribution or quantity.

In the particle selection method, particles are chosen so that their individual masses lie within ±30% of the target mass and the mean mass for each set of 20 lies within ±10% of the target mass. A typical set of particles is shown in Figure 17.

Figure 17 – A Typical Set of Particles for Breakage (Particle Selection Method)

Before commencing breakage tests on the particles, the ore density is determined by first weighing a representative sample of particles in air and then in water.

3.3.2 Cut Core Method

The cut core method uses cut pieces of quartered (slivered) drill core. Whole core or half core can be used, but when received in this form it needs to be first quartered as a preliminary step in the procedure. Once quartered, any broken or tapered ends of the quartered lengths are cut, to square them off. Before the lengths of quartered core are cut to produce the pieces for the JK Drop-Weight testing, each one is weighed in air and then in water, to obtain a density measurement and a measure of its mass per unit length.

The size fraction targeted when the cut core method is used depends on the original core diameter. The target size fraction is selected to ensure that pieces of the correct volume will have “chunky” rather than “slabby” proportions.

Having measured the density of the core, the target volume can be translated into a target mass and with the average mass per unit length also known, an average cutting interval can be determined for the core.

Sufficient pieces of the quartered core are cut to generate 100 particles. These are then divided into the five sets of 20 and broken in the JK Drop-Weight tester at the five different energy levels. Within each set, the three possible orientations of the particles are equally represented (as far as possible, given that there are 20 particles). The orientations prescribed for testing are shown in Figure 18.

Figure 18 – Orientations of Pieces for Breakage (Cut Core Method)

The cut core method cannot be used for cores with diameters exceeding 70 mm, where the particle masses would be too large to achieve the highest prescribed energy level.

3.4 SMC TEST® RESULTS

The SMC Test® results for samples Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6 from Venture Minerals are given in Table 11. This table includes the average rock density and the JK Drop-Weight index that is the direct result of the test procedure, plus the derived estimates of parameters A, b and t_a that are required for JKSimMet comminution modelling. The values determined for the M_{ia}, M_{ih} and M_{ic} parameters developed by SMCT are also presented in this table. The M_{ia} parameter represents the coarse particle component (down to 750 µm), of the overall comminution energy and can be used together with the M_{ib} (fine particle component) to estimate the total energy requirements of a conventional comminution circuit. The use of these parameters is explained further in APPENDIX C.

In the case of the Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6 samples from Venture Minerals,

the A and b estimates are based on the results of full drop-weight testing on similar ore (Main A, Main B, No. 2 A & No. 2 B). The full drop-weight test results were used to calibrate the DWi versus A and b correlations.

Table 11 - SMC Test® Results

Sample Designation	Calibration Sample	DWi kWh/m^3	DWi %	Mia kWh/t	Mih kWh/t	Mic kWh/t	A	b	SG	t_a
Main # 1	Main A and Main B	11.41	96	21.1	17.4	9.0	94.9	0.35	3.81	0.23
Main # 2	Main A and Main B	11.02	95	22.3	18.2	9.4	67.3	0.47	3.51	0.24

Note: For more details on how the M_{ia}, M_{ih} and M_{ic} parameters are derived and used, see APPENDIX C or go to the SMC Testing website at http://www.smctesting.com/about and click on the link to download Steve Morrell's paper on this subject.

The influence of particle size on the specific comminution energy needed to achieve a particular t_{10} value can also be inferred from the SMC Test® results. The energy requirements for three particle sizes, each crushed to three different t_{10} values, are presented in Table 12.

Table 12 – Energy Requirements Related to Particle Size

Sample Designation	Particle Size (mm)								
	14.5			28.9			57.8		
	t_{10} Values for Given Specific Energies (%)								
	10 kWh/t	20 kWh/t	30 kWh/t	10 kWh/t	20 kWh/t	30 kWh/t	10 kWh/t	20 kWh/t	30 kWh/t

The SMC Test® database now contains over 11,000 test results on samples representing more than 600 different deposits worldwide.

Around 99% of the DWi values lie in the range 0.5 to14.0 kWh/m^3, with soft ores being at the low end of this range and hard ores at the high end.

A cumulative graph of DWi values from the SMC Test® Database is shown in Figure 19 below. This graph can be used to compare the DWi of the material from Venture Minerals, with the entire population of ores in the SMCT database. The figures on the y-axis of the graph represent the percentages of all ores tested that are softer than the x-axis (DWi) value selected.

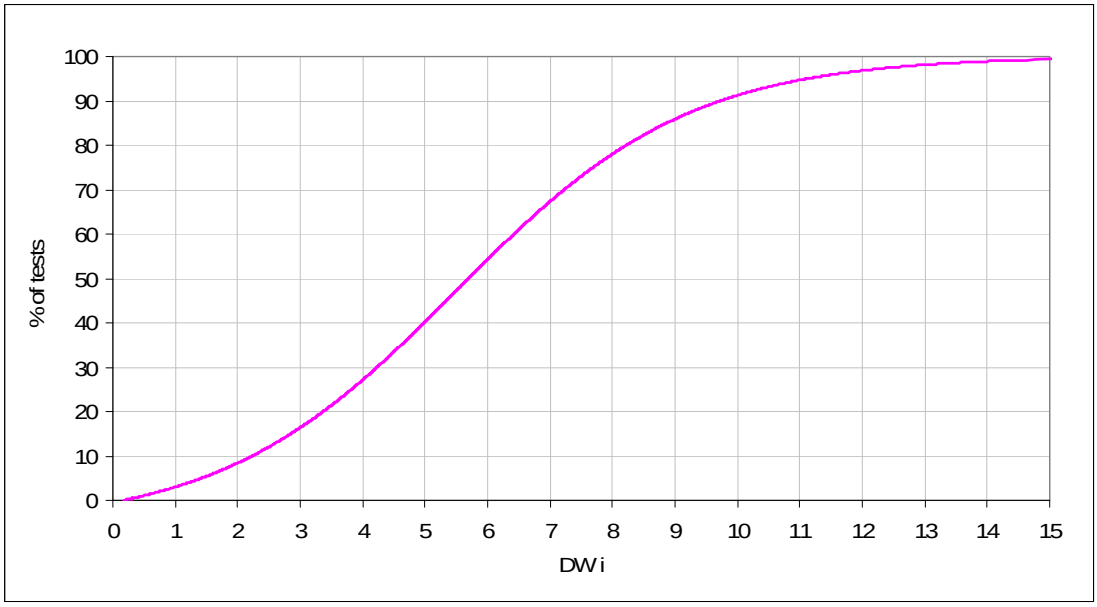

Figure 19 – Cumulative Distribution of DWi Values in SMC Test® Database

A further cumulative distribution graph is provided in Figure 20 to allow a comparison of the M_{ia}, M_{ih} and M_{ic} values obtained for the Venture Minerals material, with the entire population of values for these parameters contained in the SMCT database.

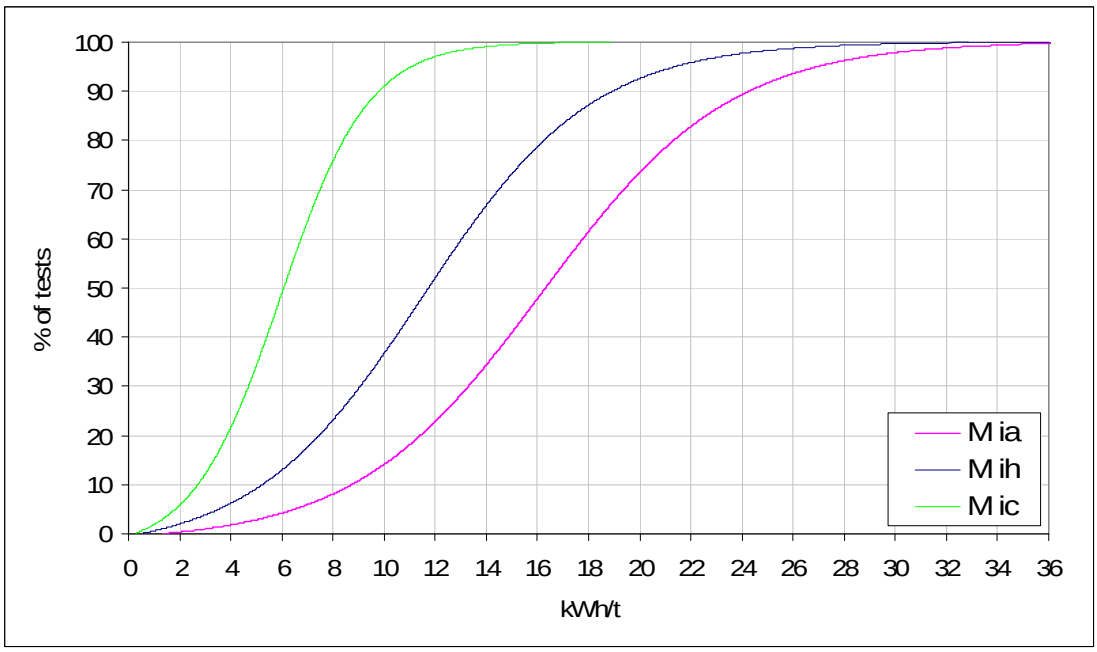

Figure 20 - Cumulative Distribution of M_{ia}, M_{ih} and M_{ic} Values in the SMCT Database

The value of A*b, which is also a measure of resistance to impact breakage, is calculated and presented in Table 13 along with indicators of how each A*b value compares with the accumulated values in the JK Drop-Weight database (from full JK Drop-Weight testing). These indicators are the Category (eg "soft" etc), the Rank (how many out of 3,825 recordings in database are harder) and the percent of database values that are harder. Note that in contrast to the DWi, a high value of A*b means that an ore is soft whilst a low value means that it is hard.

Table 13 – Derived Values for A*b and t10 at 1 kWh/t

Sample Designation	A*b				t10 @ 1 kWh/t			
	Value	Category	Rank	%	Value	Category	Rank	%
Main # 1	33.2	hard	813	21.3%	28.0	moderately hard	1196	31.3%
Main # 2	31.6	hard	658	17.2%	25.2	hard	718	18.8%
Main # 3	38.4	moderately hard	1243	32.5%	29.2	moderately hard	1385	36.2%
Main # 4	34.0	hard	867	22.7%	28.8	moderately hard	1321	34.5%
Main # 5	34.5	hard	902	23.6%	27.4	hard	1083	28.3%
Main # 6	38.4	moderately hard	1244	32.5%	28.6	moderately hard	1287	33.6%
No 2 # 1	42.8	medium	1599	41.8%	33.6	medium	2081	54.4%
No 2 # 2	33.5	hard	829	21.7%	27.2	hard	1061	27.7%
No 2 # 3	39.0	moderately hard	1302	34.0%	32.3	medium	1882	49.2%
No 2 # 4	47.7	medium	1944	50.8%	34.0	medium	2123	55.5%
No 2 # 5	40.9	moderately hard	1457	38.1%	30.9	medium	1673	43.7%
No 2 # 6	41.2	moderately hard	1476	38.6%	30.6	medium	1622	42.4%

The calculated value of t_{10} at an E_{cs} of 1 kWh/t is also shown in Table 13. This is again accompanied by Category, Rank and the percent of values in the database

that are harder, so each can be seen against the yard-stick of all other samples in the JKTech database.

The derived A*b values range from 31.6 to 47.7 giving an average of 37.9, while the t_{10} at 1 kWh/t values ranged from 25.2 to 34.0 giving an average of 29.7.

In Figure 21 and Figure 22 below, histogram style frequency distributions for the A*b values and for the t_{10} at 1 kWh/t values in the JKTech DW database are shown respectively.

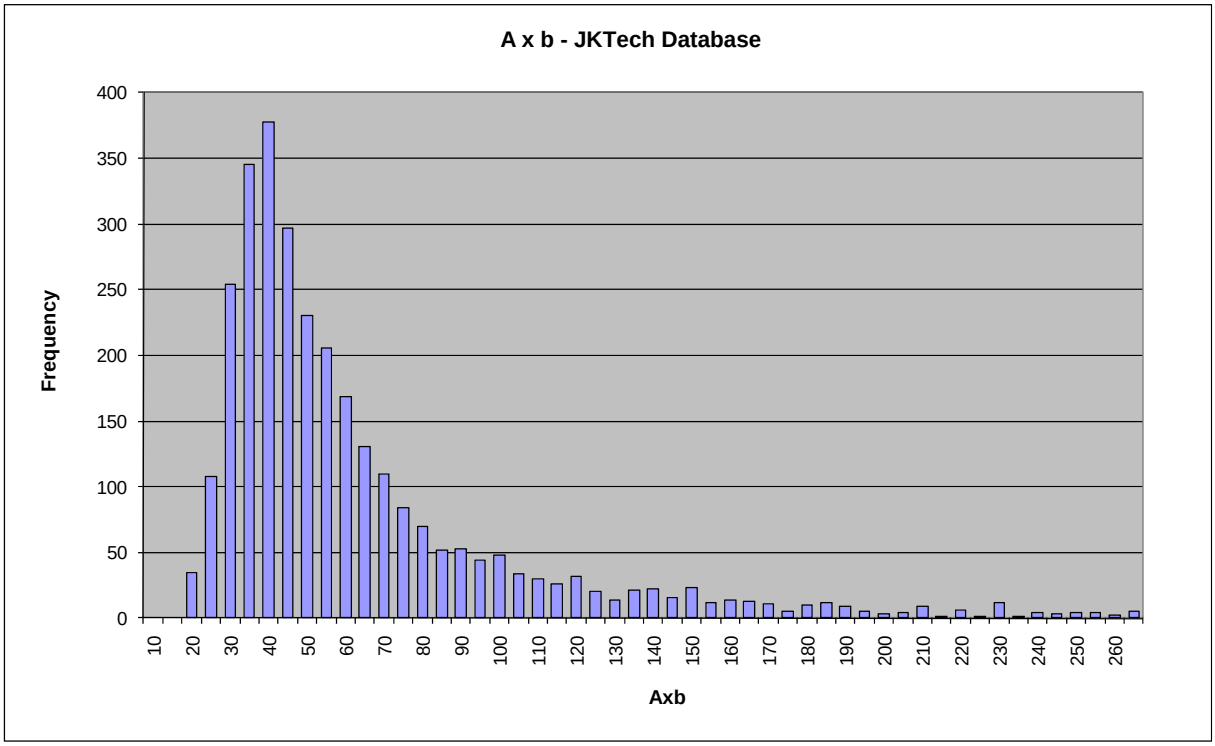

Figure 21 - Frequency Distribution of A*b in the JKTech Database

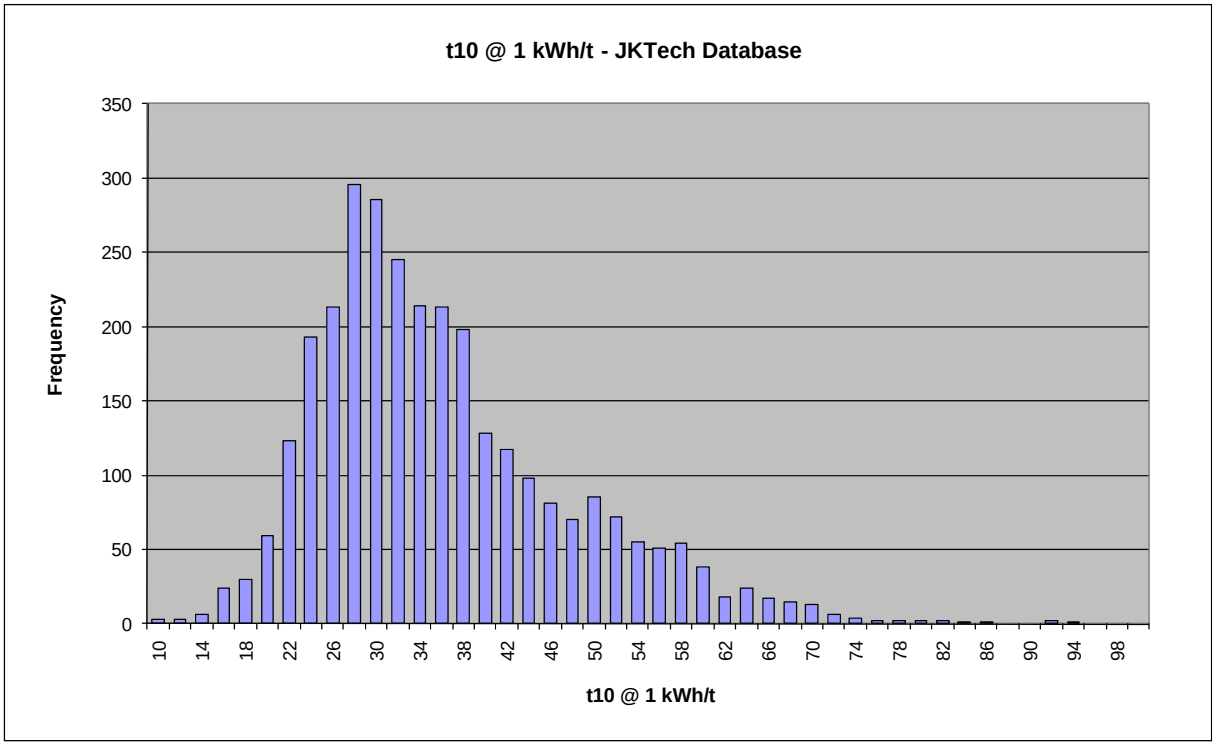

Figure 22 - Frequency Distribution of t_{10}@1kWh/t in the JKTech Database

5 DISCLAIMER

Warranty by JKTech

a. JKTech will use its best endeavours to ensure that all documentation, data, recommendations, information, advice and reports ("Material"), provided by JKTech to the client ("Recipient"), is accurate at the time of providing it.

Extent of Warranty by JKTech

b. JKTech does not make any representations as to any matter, fact or thing that is not expressly provided for in the Material.

c. JKTech does not give any warranty, nor accept any liability in connection with the Material, except to the extent, if any, required by law or specifically provided in writing by JKTech to the Recipient.

d. JKTech will not be liable to the Recipient for any claims relating to Material in any language other than in English.

e. If, apart from this Disclaimer, any warranty would be implied whether by law, custom or otherwise, that warranty is to the full extent permitted by law excluded.

f. The Recipient will promptly advise JKTech in writing of any losses, damages, compensation, liabilities, amounts, monetary and non-monetary costs and expenses ("Losses"), incurred or likely to be incurred by the Recipient or JKTech in connection with the Material, and any claims, actions, suits, demands or proceedings ("Liabilities") which the Recipient or JKTech may become liable in connection with the Material.

Indemnity and Release by the Recipient

g. The Recipient indemnifies, releases, discharges and saves harmless, JKTech against any and all Losses and Liabilities, suffered or incurred by JKTech, whether under the law of contract, tort, statutory duty or otherwise as a result of:

   i) the Recipient relying on the Material;

   ii) any liability for infringement of a third party's trade secrets, proprietary or confidential information, patents, registered designs, trademarks or names, copyright or other protected rights; and

   iii) any act or omission of JKTech, any employee, agent or permitted sub-contractor of JKTech in connection with the Material.

Limit of Liability

h. JKTech's liability to the Recipient in connection with the Material, whether under the law of contract, tort, statutory duty or otherwise, will be limited to the lesser of:

   i) the total cost of the job; or

   ii) JKTech providing amended Material rectifying the defect.

Exclusion of Consequential Loss

i. JKTech is not liable to the Recipient for any consequential, special or indirect loss (loss of revenue, loss of profits, business interruption, loss of opportunity and legal costs and disbursements), in connection with the Material whether under the law of contract, tort, statutory duty or otherwise.

Defects

j. The Recipient must notify JKTech within seven days of becoming aware of a defect in the Material. To the extent that the defect is caused by JKTech's negligence or breach of contract, JKTech may, at its discretion, rectify the defect.

Duration of Liability

k. After the expiration of one year from the date of first providing the Material to the client, JKTech will be discharged from all liability in connection with the Material. The Recipient (and persons claiming through or under the Recipient) will not be entitled to commence any action, claim or proceeding of any kind whatsoever after that date, against JKTech (or any employee of JKTech) in connection with the Material.

Contribution

l. JKTech's liability to the Recipient for any loss or damage, whether under the law of contract, tort, statutory duty or otherwise will be reduced to the extent that an act or omission of the Recipient, its employees or agents, or a third party to whom the Recipient has disclosed the Material, contributed to the loss or damage.

Severability

m. If any provision of this Disclaimer is illegal, void, invalid or unenforceable for any reason, all other provisions which are self-sustaining and capable of separate enforcement will, to the maximum extent permitted by law, be and continue to be valid and enforceable.

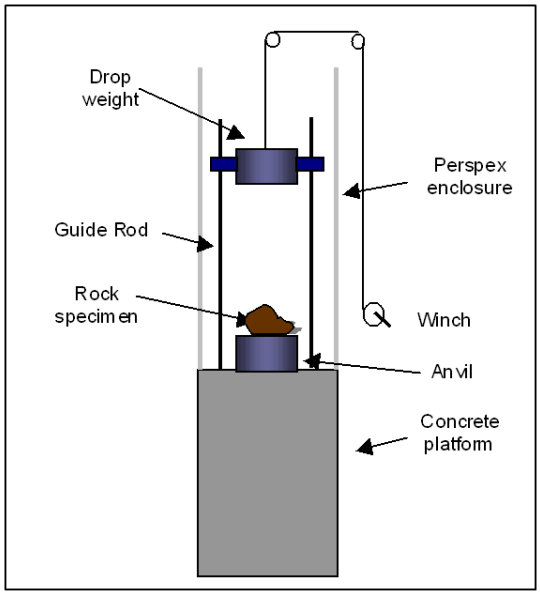
APPENDICES

APPENDIX A. BACKGROUND TO THE DROP WEIGHT TEST

A 1 INTRODUCTION

This section provides a brief description of the JK Drop-Weight test procedure.

To characterise ore breakage at different energy levels, the JKTech method uses two complimentary techniques:



1. To characterise breakage at moderate to high energy levels (i.e. impact breakage), a JK Drop-Weight device is used.

2. To characterise breakage at low energy inputs (i.e. the abrasion component of breakage), a tumbling test is used.

A 2 IMPACT BREAKAGE TESTING

The JK Drop-Weight device comprises a steel drop-weight that can be raised by a winch to a known height. A pneumatic switch releases the drop-weight, which then falls under gravity and impacts on a rock particle that is positioned on a steel anvil. The device is enclosed in Perspex shielding and incorporates a variety of features to ensure operator safety. By varying the height from which the drop-weight is released and the mass of the drop-weight, a very wide range of energy inputs can be generated. A schematic drawing of the device is given in App Figure 1.

After release, the drop-weight descends under the influence of gravity and impacts the target particle.

App Figure 1 - The JK Drop Weight Tester

The particle is broken and the drop-weight is brought to rest at a distance above the anvil approximately equal to the largest product particle. The difference in distance between the initial starting point and the final resting place of the drop-weight is used to calculate the energy that is expended in breaking the particle. Thus

$$E_i = Mg(h - x_M) \quad (1)$$

where:

E_i = energy used for breakage

M = drop-weight mass

g = gravitational constant

h = initial height of the drop-weight above the anvil

x_M = final height of the drop-weight above the anvil.

Providing the drop-weight does not rebound after impact, the application of equation (1) is valid. Where rebound occurs an additional term is required to account for the energy re-transmitted to the drop-weight. Rebound has been seen to occur only at elevated input energies. This energy will be assessed during the test work program. It is likely, however, that its magnitude will be relatively small and can be ignored with only a minimal loss in accuracy.

The assumption is made that all the energy provided is utilised in the breakage of the particle. Thus

$$E_{cs} = E_{is} = E_i / m$$

where:

E_{is} = specific input energy

E_{cs} = specific comminution energy

m = mean particle mass

To test an ore type, the original 100 kg sample is sized into selected fourth-root-of-two size fractions. Ten (10) to thirty (30) particles are required in each size fraction for each energy level, depending on particle mass. Typically fifteen (15) size/energy combinations are selected. The input energy levels for a particular test are designed to suit ore hardness but a standard set of energies are used whenever possible.

The breakage products of all particles for each size/energy combination are collected and sized. The size distribution produced is normalised with respect to the original particle size. For a wide range of energy inputs, particle sizes and ore types, the relative size distributions remain similar in shape and can be fully characterised by a single point on the distribution. The JKTech convention is to use the percentage passing one-tenth of the original particle size. This is referred to as the "t10" value.

In the manner described above, a set of t10 and Ecs values are produced for the 15 energy/size combinations.

A 3 ABRASION BREAKAGE TESTING

It is possible to characterise low energy (abrasion) breakage with a miniature drop-weight and repeated impacts. However, Leung (1987) demonstrated that a tumbling test of selected single size fractions could produce a similar result with less experimental effort.

The standard abrasion test tumbles 3 kg of -55+38 mm particles for 10 minutes at 70% critical speed in a 305 mm by 305 mm laboratory mill fitted with 4 x 6 mm lifter bars. The resulting product is then sized and the t10 value for the product is determined.

The mean particle size of the original size fraction 55 x 38 mm is 45.7 mm. The t10 size is:

1/10 x 45.7 = 4.57 mm.

A 4 USING STANDARD DW TEST RESULTS IN JKSIMMET

A 4.1 SAG/autogenous Mill Model

In the SAG/autogenous mill, both breakage mechanisms discussed in Section 2 are assumed to occur. The parameters used in the model are given in Table 1.

A 4.1.1 High Energy or Impact Breakage

To represent the impact breakage mechanism in the model, the 15 pairs of t10/Ecs data from the JK Drop-Weight test are subjected to non-linear least squares techniques to fit the following equation, which describes the relationship between breakage and impact energy:

$$t_{10} = A(1 - e^{-bE_{cs}})$$

In this equation, A and b are the fitted parameters. These parameters can then be used in the JKSimMet SAG/autogenous mill model which incorporates the same relationship.

A 4.1.2 Low Energy or Abrasion Breakage

As discussed in Section A 3, the abrasion test results in a t10 figure. The abrasion parameter used in the model, ta, is defined as

$$t_a = t_{10}/10$$

For example, if t10 = % passing 4.57 mm = 4.0%, then

$$t_a = 4.0 / 10 = 0.40$$

A 4.1.3 Combined Breakage

These two sets of parameters representing the two breakage modes are used in combination by the model to generate an ore specific appearance function. The scaling factor of 10 is applied in the calculation of ta so that the relative proportions of high and low energy breakage represented in the combined appearance function are correct.

The assumption is made that all brittle rock types break with the same general pattern and this pattern is built into the model. This assumption does not mean that the amount of energy required to achieve a particular t10 is the same for all brittle rocks. It simply means that if a single particle is broken to a particular t10 value, then the complete size distribution of the broken fragments is known.

This assumption is not perfect but is quite adequate for the purposes of the SAG/autogenous model.

To use the results of testing, the ore type parameters A and b (from JK Drop-Weight testing) and ta (from abrasion testing), are entered into the SAG/autogenous mill model in JKSimMet, together with machine dependent parameters of mill size, grate size, ball load, etc. The simulation predicts product size and mill load using appropriate breakage rates. The simulator can then also be used to predict mill performance with variations in screen and classifier configurations or even with recycle crushing.

Details of the SAG/autogenous mill model are given in Leung (1987) and Leung, Morrison, and Whiten (1987). The calculations on which the power prediction for SAG/autogenous mills is based are described in Morrell (1996).

A 4.2 Crusher Model

For the crusher model, only the high energy or impact breakage test results are used. These are presented in a somewhat different manner from the SAG/autogenous mill model.

The assumption that all brittle rocks break with the same breakage pattern is not made and the pattern for the ore under test is used. The parameters used by the crusher model are tabulated in the results section of this report. The appearance function defines the shape of the breakage distribution curve at various degrees of "broken-ness", as defined by t10. The specific comminution energy table defines the amount of energy required to achieve varying levels of "broken-ness". The form of the specific comminution energy table reflects the fact that the energy required to achieve a certain degree of breakage is sometimes found to be dependent on the initial particle size.

Details of the crusher model including power prediction are described in Andersen and Napier-Munn (1988).

A 4.3 Limitations

Experience to date demonstrates that the JK Drop-Weight test is appropriate for brittle ores over a wide range of hardness. However, it is not useful for ores which

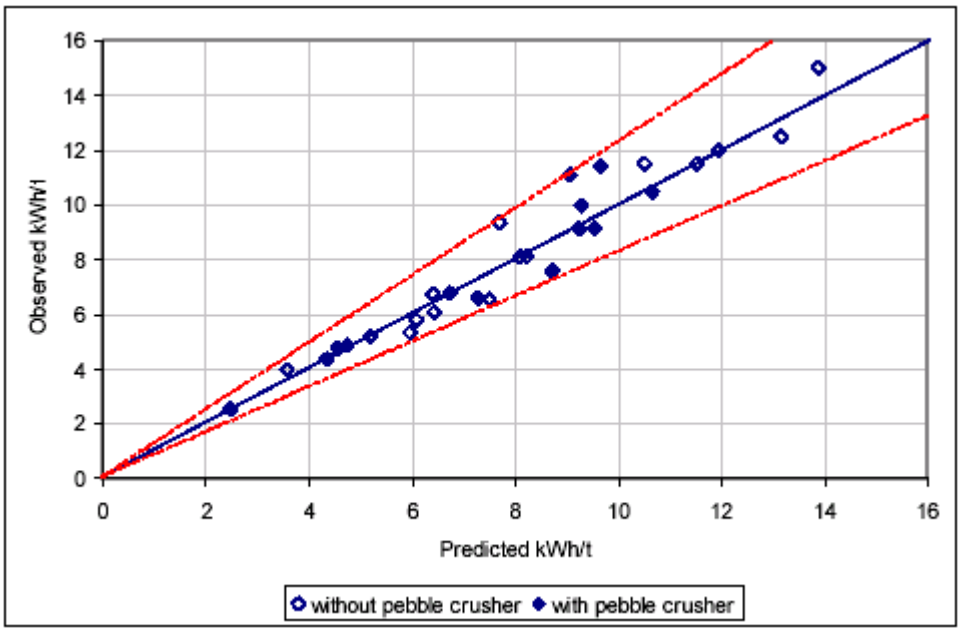
undergo plastic deformation rather than brittle fracture, such as those of high clay content.

The testing procedure is limited by the maximum particle size tested. If the ore is fractured or weaker at larger particle sizes, then JKSimMet simulations will be conservative.

For autogenous mills it is essential to have competent material in the range 150 mm to 100 mm in the feed to form the media. If autogenous milling is seriously contemplated, testing of media competency at larger particle sizes should be conducted. This can be achieved by JK Drop-Weight testing, media competency testing or full pilot plant testing.

APPENDIX B. BACKGROUND TO THE SMC TEST®

B 1 HOW THE SMC TEST® RESULTS ARE USED



The SMC Test® generates a relationship between specific input energy (kWh/t) and the percent of broken product passing a specified sieve size. The results are used to determine the JK Drop-Weight index (DWi), which is a measure of the strength of the rock when broken under impact conditions. The DWi is directly related to the JK rock breakage parameters A and b and hence can be used to estimate the values of these parameters.

Provision of a relatively low cost method of estimating the A and b parameters opens the possibility of incorporating these data into mine and mill planning operations. However a number of full JK Drop-Weight tests is still recommended for any particular orebody, to ensure that an accurate correlation between the DWi and the A and b parameters is available. The number of full JK Drop-Weight tests required for a given orebody will depend on its variability and should at least cover the major recognised ore types.

The A and b parameters are used in AG/SAG mill models, such as those in JKSimMet, for predicting how the rock will break inside the mill. From this description the models can predict what the throughput, power draw and product size distribution will be (Napier-Munn et al (1996)). Modelling also enables a detailed flowsheet to be built up of the comminution circuit response to changes in ore type. It also allows optimisation strategies to be developed to overcome any deleterious changes in circuit performance predicted from differences in ore type when such changes are indicated by the SMC Test®. These strategies can include both changes to how mills are operated (eg ball load, speed etc) and changes to feed size distribution through modification of blasting practices and primary crusher operation (mine-to-mill).

The mine to mill models require information on rock mass competence such as provided by the point load index. The DWi is correlated with the point load index and hence can also be used in blast fragmentation modelling where direct measurements of point load index are not available.

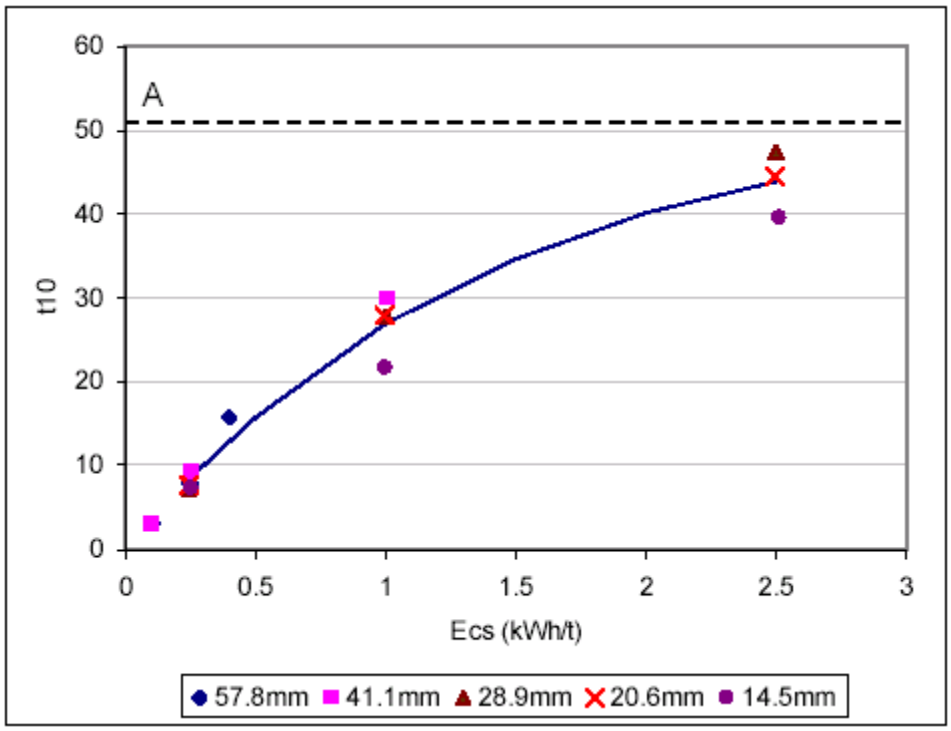
The DWi is related to the resistance of a rock to breakage under impact. SMCT has developed a series of equations that relate the DWi to the specific energy (kWh/t) requirements of complete AG and SAG mill circuits. These equations take into consideration factors such as ball charge, feed size, aspect ratio, whether the mill is operated with or without a pebble crusher and whether it is closed with a fine classifier such as a cyclone. The ability of these equations to predict AG/SAG mill circuit specific energy is illustrated in App Figure 2. The data shown cover 19 different operations and include Cu, Au, Ni and Pb/Zn ores.

App Figure 2 - Mill Power Prediction Based on DWi

It should be noted that the parameter ta, which is the parameter representing the low energy abrasion component of breakage, is not yielded by the SMC Test®. This parameter is derived from a tumbling test that is carried out as part of the full JK Drop-Weight test. The fact that it is also required as an input to the JKSimMet SAG/AG models provides a further reason for ensuring that some full JK Drop-Weight tests are also performed to represent at least the main rock types of an orebody.

B 2 IMPACT COMMINUTION THEORY

When a rock fragment is broken, the degree of breakage can be characterised by the "t10" parameter. The t10 value is the percentage of the original rock mass that passes a screen aperture one tenth of the original rock fragment size. This parameter allows the degree of breakage to be compared across different starting sizes.



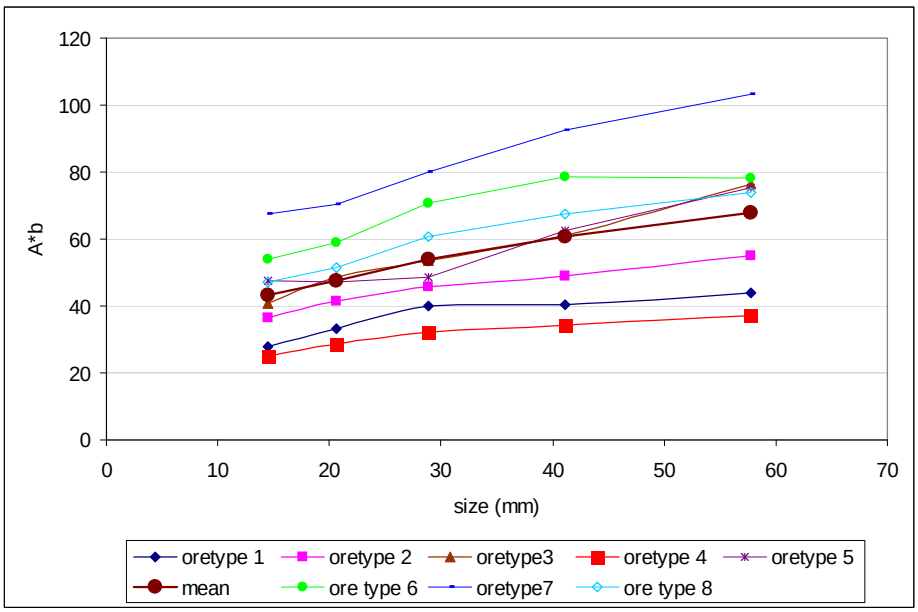
The specific comminution energy (Ecs) has the units kWh/t and is the energy applied during impact breakage. As the impact energy is varied, so does the t10 value vary in response. Higher impact energies produce higher values of t10, which of course means products with finer size distributions.

The equation describing the relationship between the t10 and Ecs is given below.

$$t_{10} = A (1 - e^{-b.Ecs})$$

As can be seen from this equation, there are two rock breakage parameters A and b that relate the t10 (size distribution index) to the applied specific energy (Ecs). These parameters are ore specific and are normally determined from a full JK Drop-Weight test.

A typical plot of t10 vs Ecs from a JK Drop-Weight test is shown in App Figure 3. The relationship is characterised by the two-parameter equation above, where t10 is the dependent variable.

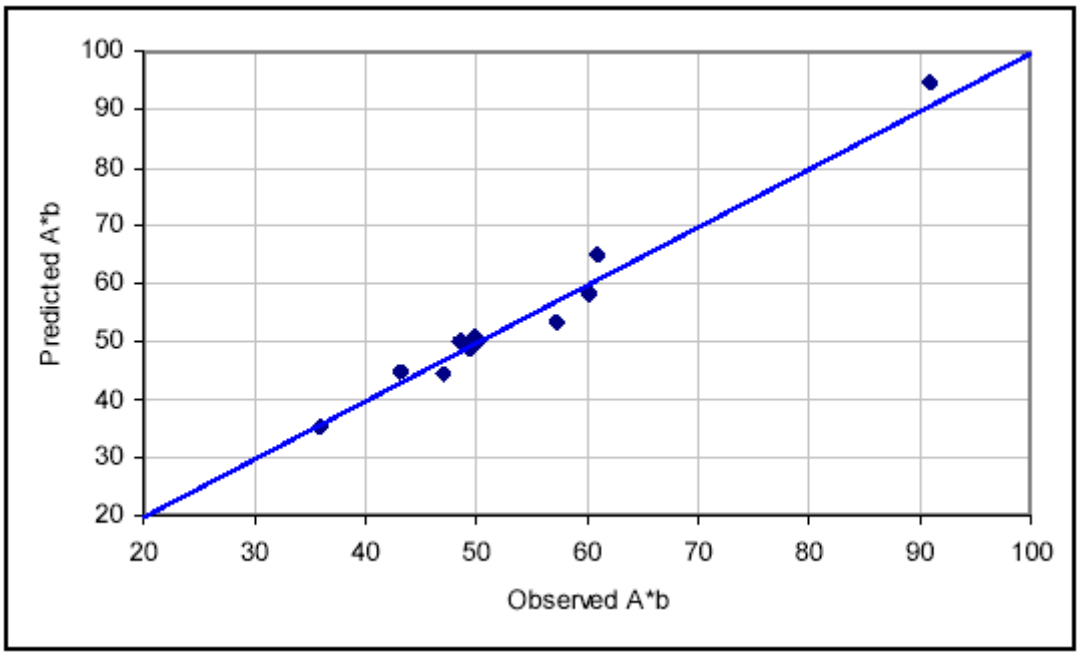


App Figure 3 - Typical t_{10} v Ecs Plot

The t10 can be thought of as a “fineness index” with larger values of t10 indicating a finer product size distribution. The value of parameter A is the limiting value of t10. This limit indicates that at higher energies, little additional size reduction occurs as the Ecs is increased beyond a certain value. A*b is the slope of the curve at ‘zero’ input energy and is generally regarded as an indication of the strength of the rock, lower values indicating a higher strength.

The A and b parameters can also be used with equation 1 to generate a table of Ecs values, given a range of t10 values. Such a table is used in crusher modelling to predict the power requirement of the crusher given a feed and a product size specification.

The DWi can be used to estimate the JK rock breakage parameters A and b by utilizing the fact that there is usually a pronounced (and ore specific) trend to decreasing rock strength with increasing particle size. This trend is illustrated in App Figure 4 which shows a plot of A*b versus particle size for a number of different rock types.



App Figure 4 - Size Dependence of A*b for a Range of Ore Types

In the case of a conventional JK Drop-Weight test these values are effectively averaged and a mean value of A and b is reported. The SMC Test® uses a single size and makes use of relationships such as that shown in App Figure 4 to predict the A and b of the particle size that has the same value as the mean for a full JK Drop-Weight test.

An example of this is illustrated in App Figure 5 - Predicted v Observed A*b

where the observed values of the product A*b are plotted against those predicted using the DWi. Each of the data points in App Figure 5 is a result from a different ore type within an orebody.

App Figure 5 - Predicted v Observed A*b

APPENDIX C. USE OF THE Mia, Mib, Mih, Mic IN PREDICTING COMMINUTION CIRCUIT SPECIFIC ENERGY

C 1 INTRODUCTION

The following technical note describes the recently extended use of the SMC Test® to include crushers and HPGRs in determining the overall specific energy demand of comminution circuits. It builds on previous work which included tumbling mills only and should be read in conjunction with an earlier technical note dated September 2007 entitled "*Use of the SMC Test® in Predicting Total Comminution Circuit Specific Energy"* as well as published papers: Morrell, 2008a, 2008b*.* This enhancement now enables the SMC Test® to be used in conjunction with the Bond ball work index test to predict the specific energy of comminution circuits where such circuits include combinations of any of the following equipment:

- AG and SAG mills
- Ball mills
- Rod mills
- Crushers
- High pressure Grinding Rolls (HPGR)

C 2 EQUATIONS

C 2.1 General

The approach divides comminution equipment into three categories:

- Tumbling mills, eg AG, SAG, rod and ball mills
- Conventional reciprocating crushers, eg jaw, gyratory and cone
- HPGRs

Tumbling mills are described using 2 indices: M_{ia} and M_{ib}

Crushers have one index: M_{ic}

HPGRs have one index: M_{ih}

For tumbling mills the 2 indices relate to "coarse" and "fine" ore properties plus an efficiency factor which represents the influence of a pebble crusher in AG/SAG mill circuits. "Coarse" in this case is defined as spanning the size range from a P_{80} of 750 µm up to the P_{80} of the product of the last stage of crushing or HPGR size reduction prior to grinding. "Fine" covers the size range from a P_{80} of 750 µm down to P_{80} sizes typically reached by conventional ball milling, ie about 45 µm. The choice of 750 µm as the division between "coarse" and "fine" particle sizes was determined during the development of the technique and was found to give the best overall results across the range of plants in SMCT's database. Implicit in the approach is that distributions are parallel and linear in log-log space.

The work index covering grinding in tumbling mills of coarse sizes is labelled M_{ia}. The work index covering grinding of fine particles is labelled M_{ib}. M_{ia} values are provided as a standard output from a SMC Test® (Morrell, 2004[a]) whilst M_{ib} values can be determined using the data generated by a conventional Bond ball mill work index test (M_{ib} is NOT the Bond ball work index). M_{ic} and M_{ih} values are also provided as a standard output from a SMC Test®.

The general size reduction equation is as follows (Morrell, 2004[b]):

$$W_i = M_i 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \qquad (1)$$

Where:

M_i = Work index related to the breakage property of an ore (kWh/tonne). For grinding from the product of the final stage of crushing to a P_{80} of 750 µm (coarse particles) the index is labelled M_{ia} and for size reduction from 750 µm to the final product P_{80} normally reached by conventional ball mills (fine particles) it is labelled M_{ib}. For conventional crushing M_{ic} is used and for HPGRs M_{ih} is used.

W_i = Specific comminution (kWh/tonne)

x_2 = 80% passing size for the product (µm)

x_1 = 80% passing size for the feed (µm)

$f(x_j)$ = $-(0.295 + x_j/1000000)$ (Morrell, 2006) (2)

For tumbling mills the specific comminution energy (Wi) relates to the power at the pinion or for gearless drives - the motor output. For HPGRs it is the energy inputted to the rolls, whilst for conventional crushers Wi relates to the specific energy as determined using the motor input power less the no-load power.

C 2.2 Specific Energy Determination for Comminution Circuits

The total specific energy (W_T) to reduce in size primary crusher product to final product is given by:

$W_T = W_a+W_b+W_c+W_h+W_s$ (3)

Where:

W_a = specific energy to grind coarser particles in tumbling mills

W_b = specific energy to grind finer particles in tumbling mills

W_c = specific energy for conventional crushing

W_h = specific energy for HPGRs

W_s = specific energy correction for size distribution

Clearly only the *W* values associated with the relevant equipment in the circuit being studied are included in equation 3.

C 2.2.1 Tumbling mills

For coarse particle grinding in tumbling mills equation 1 is written as:

$$W_a = K_1 M_{ia} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (4)$$

Where:

K_1 = 1.0 for all circuits that do not contain a recycle pebble crusher and 0.95 where circuits do have a pebble crusher

x_1 = P_{80} (µm) of the product of the last stage of crushing before grinding

x_2 = 750 µm

M_{ia} = Coarse ore work index and is provided directly by SMC Test®

For fine particle grinding equation 1 is written as:

$$W_b = M_{ib} 4\left(x_3^{\,f(x_3)} - x_2^{\,f(x_2)}\right) \quad (5)$$

Where:

x_2 = 750 µm

x_3 = P_{80} (µm) of final grind

M_{ib} = Provided by data from the standard Bond ball work index test using the following equation (Morrell, 2006):

$$M_{ib} = \frac{18.18}{P_1^{0.295}(Gbp)\left(p_{80}^{\,f(p_{80})} - f_{80}^{\,f(f_{80})}\right)} \quad (6)$$

Where:

M_{ib} = fine ore work index (kWh/tonne)

P_1 = closing screen size (µm)

Gbp = net grams of screen undersize per mill revolution

p_{80} = 80% passing size of the product (µm)

f_{80} = 80% passing size of the feed (µm)

Note that the Bond ball work index test should be carried out with a closing screen size chosen to give a final product P_{80} similar to that intended for the full-scale circuit.

C 2.2.2 Conventional Crushers

Equation 1 for conventional crushers is written as:

$$W_c = K_2 M_{ic} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (7)$$

K_2 = 1.0 for all crushers operating in closed circuit with a classifying screen. If the crusher is in open circuit, eg pebble crusher in a AG/SAG circuit, K2 takes the value of 1.19.

x_1 = P_{80} (µm) of the circuit feed

x_2 = P_{80} (µm) of the circuit product

M_{ic} = Crushing ore work index and is provided directly by SMC Test®

C 2.2.3 HPGR

Equation 1 for conventional crushers is written as:

$$W_h = K_3 M_{ih} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (8)$$

K_3 = 1.0 for all HPGRs operating in closed circuit with a classifying screen. If the HPGR is in open circuit, K3 takes the value of 1.19.

x_1 = P_{80} (µm) of the circuit feed

x_2 = P_{80} (µm) of the circuit product

M_{ih} = HPGR ore work index and is provided directly by SMC Test®

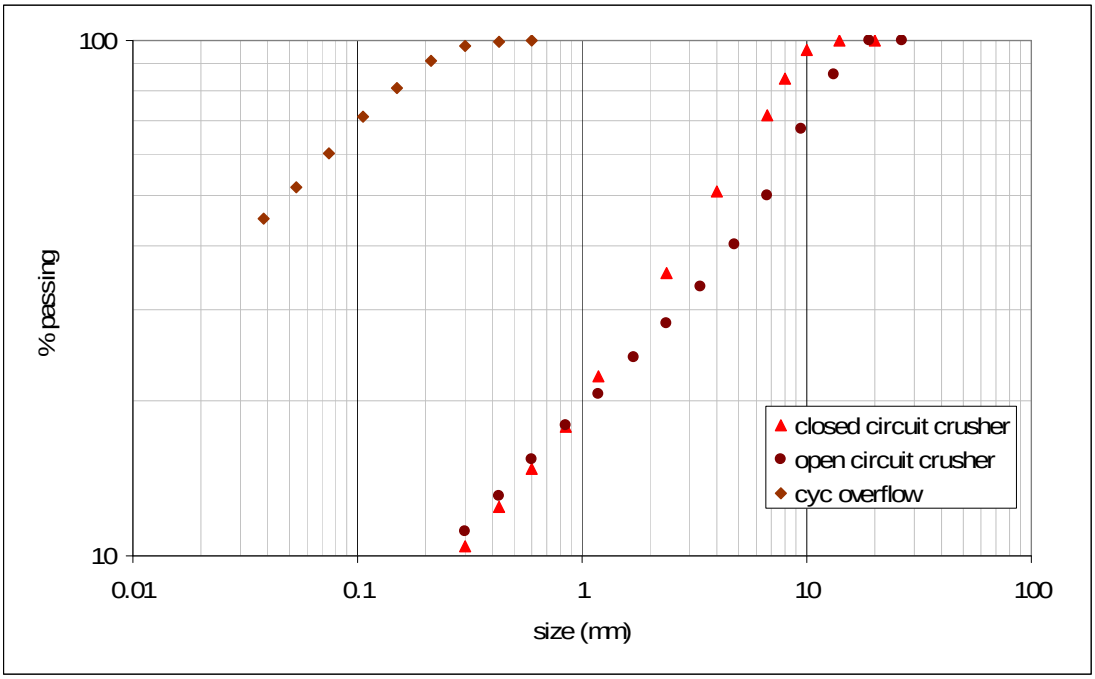
C 2.2.4 Specific Energy Correction for Size Distribution (Ws)

Implicit in the approach described in this paper is that the feed and product size distributions are parallel and linear in log-log space. Where they are not, allowances (corrections) need to be made. By and large, such corrections are most likely to be necessary (or are large enough to be warranted) when evaluating circuits in which closed circuit secondary/tertiary crushing is followed by ball milling. This is because such crushing circuits tend to produce a product size distribution which is relatively steep when compared to the ball mill circuit cyclone overflow. This is illustrated in App Figure 6, which shows measured distributions from an open and closed crusher circuit as well as a ball mill cyclone overflow. The closed circuit crusher distribution can be seen to be relatively steep compared with the open circuit crusher distribution and ball mill cyclone overflow. Also the open circuit distribution more closely follows the gradient of the cyclone overflow. If a ball mill circuit were to be fed 2 distributions, each with same P_{80} but with the open and closed circuit gradients in App Figure 6, the closed circuit distribution would require more energy to grind to the final P_{80}. How much more energy is required is difficult to determine. However, for the purposes of this approach it has been assumed that the additional specific energy for ball milling is the same as the difference in specific energy between open and closed crushing to reach the nominated ball mill feed size. This assumes that a crusher would provide this energy. However, in this situation the ball mill has to supply this energy and it has a different (higher) work index than the crusher (ie the ball mill is less energy efficient than a crusher and has to input more energy to do the same amount of size reduction). Hence from equation 7, to crush to the ball mill circuit feed size (x_2) in open circuit requires specific energy equivalent to:

$$W_c = 1.19 * M_{ic} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (9)$$

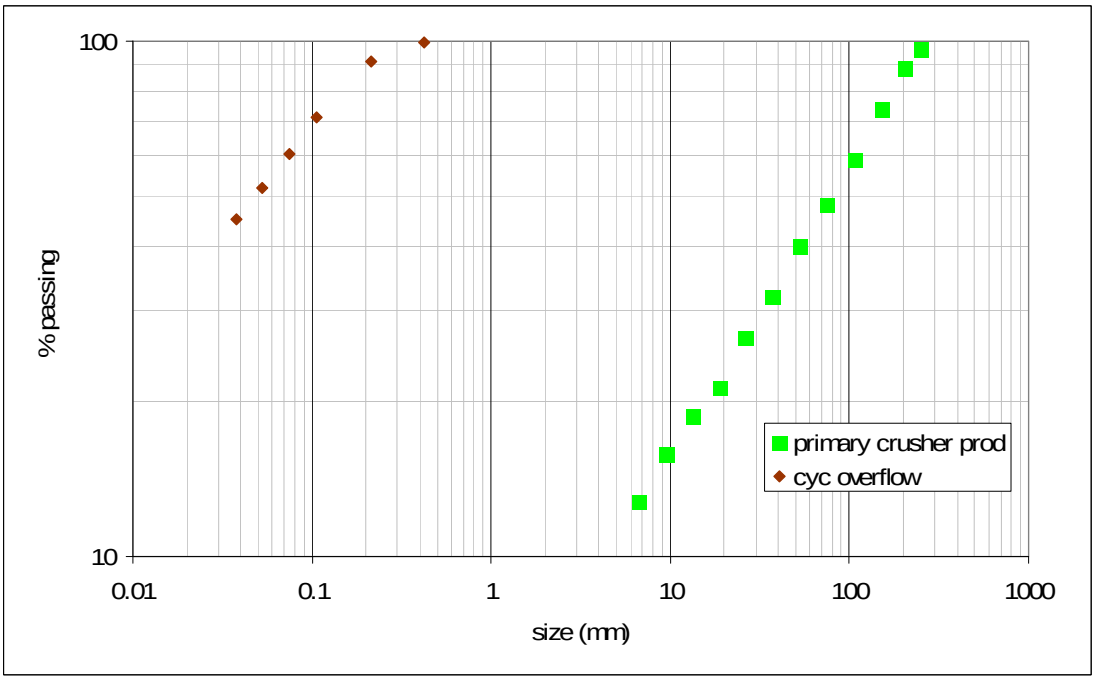
For closed circuit crushing the specific energy is:

$$W_c = 1 * M_{ic} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (10)$$



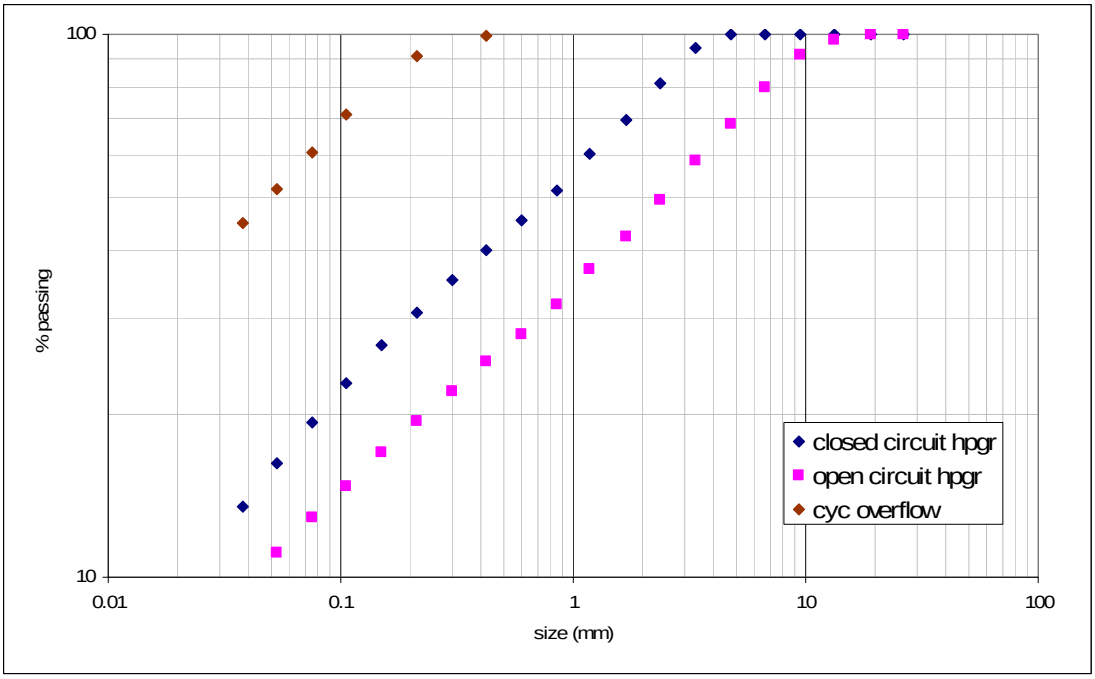
The difference between the two (eq 9 – eq 10) has to be provided by the milling circuit with an allowance for the fact that the ball mill, with its lower energy efficiency, has to provide it and not the crusher. This is what is referred to in equation 3 as W_s and for the above example is therefore represented by:

$$W_s = 0.19 * M_{ia} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (11)$$



Note that in equation 11 M_{ic} has been replaced with M_{ia}, the coarse particle tumbling mill grinding work index.

In AG/SAG based circuits the need for W_s appears to be unnecessary as App Figure 7 illustrates. Primary crusher feeds often have the shape shown in App Figure 7 and this has a very similar gradient to typical ball mill cyclone overflows. A similar situation appears to apply with HPGR product size distributions, as illustrated in App Figure 8. Interestingly SMCT's data show that for HPGRs, closed circuit operation appears to require a lower specific energy to reach the same P_{80} as in open circuit, even though the distributions for open and closed circuit look to have almost identical gradients. Closer examination of the distributions in fact shows that in closed circuit the final product tends to have slightly less very fine material, which may account for the different energy requirements between the two modes of operation. It is also possible that recycled material in closed circuit is inherently weaker than new feed, as it has already passed through the HPGR previously and may have sustained micro-cracking. A reduction in the Bond ball mill work index as measured by testing HPGR products compared it to the Bond ball mill work index of HPGR feed has been noticed in many cases in the laboratory (see next section) and hence there is no reason to expect the same phenomenon would not affect the recycled HPGR screen oversize.



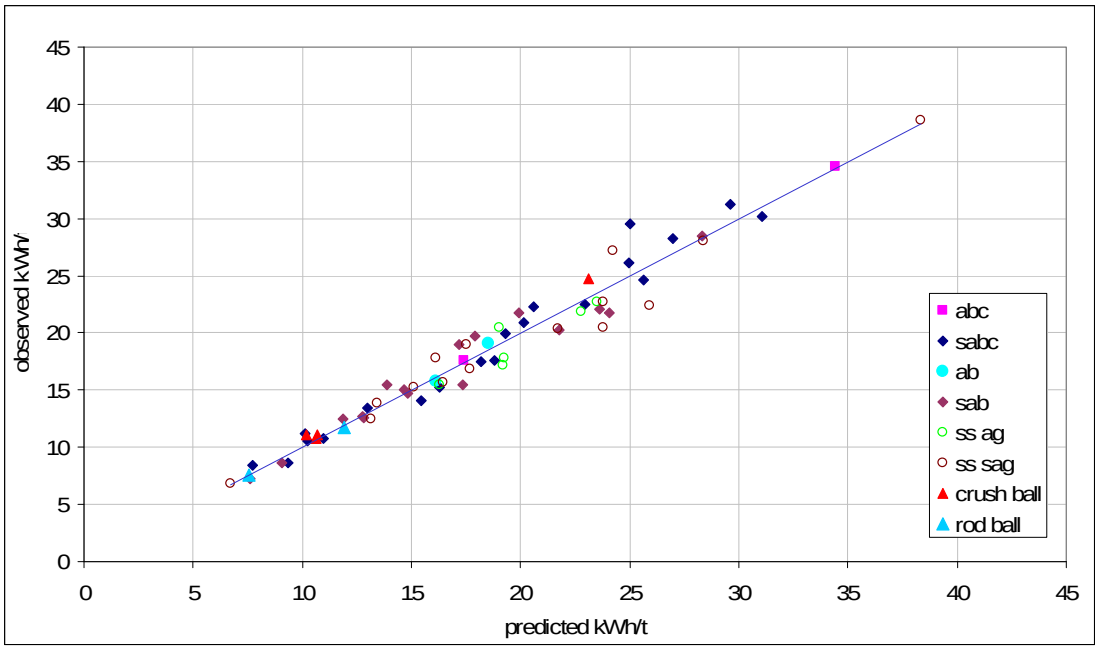
It follows from the above arguments that in HPGR circuits, which are typically fed with material from closed circuit secondary crushers, a similar feed size distribution correction should also be applied. However, as the secondary crushing circuit uses such a relatively small amount of energy compared to the rest of the circuit (as it crushes to a relatively coarse size) the magnitude of size distribution correction is very small indeed – much smaller than the error associated with the technique - and hence may be omitted in calculations.

App Figure 6 – Examples of Open and Closed Circuit Crushing Distributions Compared with a Typical Ball Mill Cyclone Overflow Distribution

App Figure 7 – Example of a Typical Primary Crusher (Open and Circuit) Product Distribution Compared with a Typical Ball Mill Cyclone Overflow Distribution

App Figure 8 – Examples of Open and Closed Circuit HPGR Distributions Compared with a Typical Ball Mill Cyclone Overflow Distribution

C 2.2.5 Weakening of HPGR Products



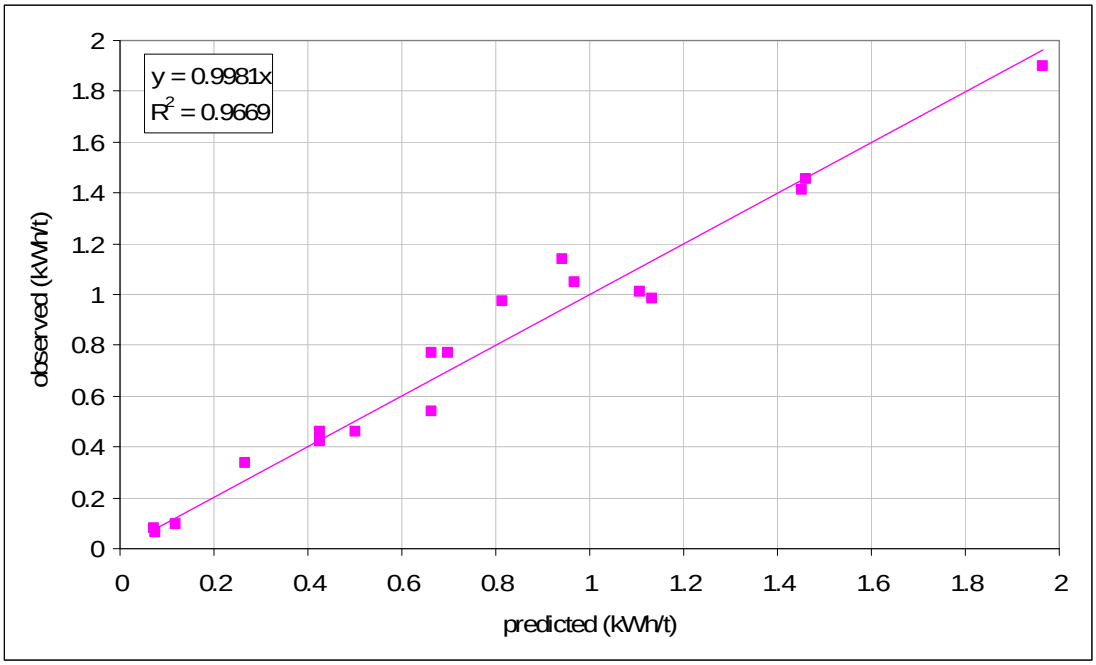
As mentioned in the previous section, laboratory experiments have been reported by various researchers in which the Bond ball work index of HPGR products is less than that of the feed. The amount of this reduction appears to vary with both material type and the pressing force used. Observed reductions in the Bond ball work index have typically been in the range 0-10%. In the approach described in this paper no allowance has been made for such weakening. However, if HPGR products are available which can be used to conduct Bond ball work index tests on then M_{ib} values obtained from such tests can be used in equation 5. Alternatively the M_{ib} values from Bond ball mill work index tests on HPGR feed material can be reduced by an amount that the user thinks is appropriate. Until more data become available from full scale HPGR/ball mill circuits it is suggested that, in the absence of Bond ball mill work index data on HPGR products, the M_{ib} results from HPGR feed material are reduced by no more than 5% to allow for the effects of micro-cracking.

C 3 VALIDATION

C 3.1 Tumbling Mill Circuits

The approach described in the previous section was applied to 65 industrial data sets. The results are shown in App Figure 9. In all cases, the specific energy relates to the tumbling mills contributing to size reduction from the product of the final stage of crushing to the final grind. Data are presented in terms of equivalent specific energy at the pinion. In determining what these values were on each of the plants in the data base it was assumed that power at the pinion was 93.5% of the measured

gross (motor input) power, this figure being typical of what is normally accepted as being reasonable to represent losses across the motor and gearbox. For gearless drives (so-called wrap-around motors) a figure of 97% was used.

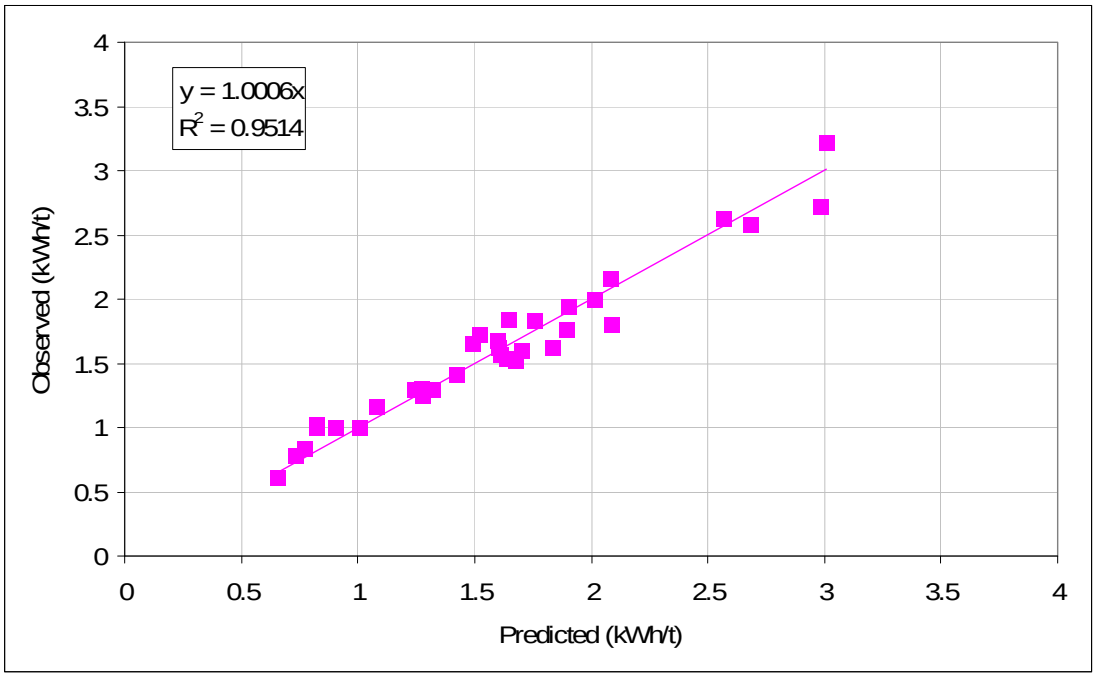


App Figure 9 – Observed vs Predicted Tumbling Mill Specific Energy

C 3.2 Conventional Crushers

Validation of equation 1 used 10 different crushing circuits (18 data sets), including secondary, tertiary and pebble crushers in AG/SAG circuits. Observed vs predicted specific energies are given in App Figure 10. The observed specific energies were calculated from the crusher throughput and the net power draw of the crusher as defined by:

Net Power = Motor Input Power – No Load Power (12)



No-load power tends to be relatively high in conventional crushers and hence net power is significantly lower than the motor input power. From examination of the 18 crusher data sets the motor input power was found to be on average 35% higher than the net power.

App Figure 10 – Observed vs Predicted Conventional Crusher Specific Energy

C 3.3 HPGRs

Validation of equation 1 for HPGRs used data from 18 different circuits (35 data sets) including laboratory, pilot and industrial scale equipment. Observed vs predicted specific energies are given in App Figure 11. The data relate to HPGRs operating with specific grinding forces typically in the range 2.5-3.5 N/mm^2. The observed specific energies relate to power delivered by the roll drive shafts. Motor input power for full scale machines is expected to be 8-10% higher.

App Figure 11 – Observed vs Predicted HPGR Specific Energy

C 4 WORKED EXAMPLES

A SMC Test® and Bond ball work index test were carried out on a representative ore sample. The following results were obtained:

SMC Test:

M_{ia} = 19.4 kWh/t

M_{ic} = 7.2 kWh/t

M_{ih} = 13.9 kWh/t

Bond test carried out with a 150 micron closing screen:

M_{ib} = 18.8 kWh/t

Three circuits are to be evaluated:

SABC

HPGR/ball mill

Conventional crushing/ball mill

The overall specific grinding energy to reduce a primary crusher product with a P_{80} of 100 mm to a final product P_{80} of 106 µm needs to be estimated.

C 4.1 SABC Circuit

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 0.95 * 19.4 * 4 * \left(750^{\ -(0.295+750/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 9.6 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8 * 4 * \left(106^{\ -(0.295+106/1000000)} - 750^{\ -(0.295+750/1000000}\right)$$

= 8.4 kWh/t

Pebble crusher specific energy

In this circuit, it is assumed that the pebble crusher feed P_{80} is 52.5mm. As a rule of thumb this value can be estimated by assuming that it is 0.75 of the nominal pebble port aperture (in this case the pebble port aperture is 70mm). The pebble crusher is set to give a product P_{80} of 12mm. The pebble crusher feed rate is expected to be 25% of new feed tph.

Combining eq 2 and 7:

$$W_c = 1.19 * 7.2 * 4 * \left(12000^{\ -(0.295+12000/1000000)} - 52500^{\ -(0.295+52500/1000000}\right)$$

= 1.12 kWh/t when expressed in terms of the crusher feed rate

= 1.12 * 0.25 kWh/t when expressed in terms of the SABC circuit new feed rate

= 0.3 kWh/t of SAG mill circuit new feed

Total net comminution specific energy:

From eq 3:

W_T = 9.6 + 8.4 + 0.3 kWh/t

= 18.3 kWh/t

C 4.2 HPGR/Ball Milling Circuit

In this circuit primary crusher product is reduced to a HPGR circuit feed P_{80} of 35 mm by closed circuit secondary crushing. The HPGR is also in closed circuit and reduces the 35 mm feed to a circuit product P_{80} of 4 mm. This is then fed to a closed circuit ball mill which takes the grind down to a P_{80} of 106 µm.

Secondary crushing specific energy

Combining eq 2 and 7:

$$W_c = 1 * 7.2 * 4 * \left(35000^{\ -(0.295+35000/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 0.6 kWh/t

HPGR specific energy

Combining eq 2 and 8:

$$W_c = 1*13.9*4*\left(4000^{\,-(0.295+4000/1000000)} - 35000^{\,-(0.295+35000/1000000)}\right)$$

= 2.9 kWh/t

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 1*19.4*4*\left(750^{\,-(0.295+750/1000000)} - 4000^{\,-(0.295+4000/1000000)}\right)$$

= 4.5 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8*4*\left(106^{\,-(0.295+106/1000000)} - 750^{\,-(0.295+750/1000000)}\right)$$

= 8.4 kWh/t

Total net comminution specific energy:

From eq 3:

W_T = 4.5 + 8.4 + 0.6 + 2.9 kWh/t

= 16.4 kWh/t

C 4.3 Conventional Crushing/Ball Milling Circuit

In this circuit primary crusher product is reduced in size to P_{80} of 6.5 mm via a secondary/tertiary crushing circuit (closed). This is then fed to a closed circuit ball mill which grinds to a P80 of 106 µm.

Secondary/tertiary crushing specific energy

Combining eq 2 and 7:

$$W_c = 1*7.2*4*\left(6500^{\,-(0.295+6500/1000000)} - 100000^{\,-(0.295+100000/1000000)}\right)$$

= 1.7 kWh/t

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 1*19.4*4*\left(750^{\,-(0.295+750/1000000)} - 6500^{\,-(0.295+6500/1000000)}\right)$$

= 5.5 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8 * 4 * \left(106^{\ -(0.295+106/1000000)} - 750^{\ -(0.295+750/1000000}\right)$$

= 8.4 kWh/t

Size distribution correction

$$W_s = 0.19 * 19.4 * 4 * \left(6500^{\ -(0.295+6500/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 0.9 kWh/t

Total net comminution specific energy:

From eq 3:

W_T = 5.5 + 8.4 + 1.7 + 0.9kWh/t

= 16.5 kWh/t

1 INTRODUCTION

JKDrop-Weight & SMC data for sixteen samples from Venture Minerals were received from ALS Ammtec SA on July 19, 2012, by JKTech for JKDrop-Weight & SMC test analysis. The samples were identified as Main A, Main B, No. 2 A, No. 2 B, Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6. The data were analysed to determine the JKSimMet comminution parameters. SMC test results were forwarded to SMC Testing Pty Ltd for the analysis. The samples had been subjected to JKDrop-Weight testing (Main A, Main B, No. 2 A & No. 2 B) & SMC testing (Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6). Analysis and reporting were completed on July 24, 2012.

2 THE JK DROP-WEIGHT TEST

2.1 INTRODUCTION

The JKTech Drop-Weight test provides ore specific parameters for use in the JKSimMet Mineral Processing Simulator software. In JKSimMet, these parameters are combined with equipment details and operating conditions to analyse and/or predict SAG/autogenous mill performance. The same test procedure also provides ore type characterisation for the JKSimMet crusher model. These ore specific parameters have been calculated from the test results and are supplied to Venture Minerals Limited in this report as part of the standard procedure.

2.2 DROP-WEIGHT TEST PROCEDURE

Details of the JK Drop-Weight test procedure can be found in APPENDIX A.

2.3 INTERPRETATION OF DW TEST RESULTS

2.3.1 Resistance to Impact Breakage

One of the problems with the functional form used to represent the t_{10} v E_{cs} relationship is that the parameters A and b are not independent and thus cannot be used directly for comparisons between ore types. Two alternative parameters give a better comparison. These are the product A*b and the t_{10} achieved by the application of 1.0 kWh/t of Specific Comminution Energy (E_{cs}). For both of these parameters, a smaller number means a greater resistance to impact breakage.

2.3.2 Resistance to Abrasion Breakage

Resistance to abrasion is indicated by the t_a parameter. As with parameter A*b, a smaller value of t_a indicates more resistance, this time to abrasion breakage.

2.3.3 Effect of Particle Size on Resistance to Impact Breakage

Variation of impact resistance with particle size is important for crusher power draw calculations and SAG/autogenous mill media competency considerations. Some ores exhibit a significant decrease in impact resistance with increasing particle size while others show no variation with size. The opposite trend of increasing impact resistance with increasing particle size is extremely rare.

The trend most frequently observed is for there to be decreasing slope with decreasing energy (E_{cs} values). However, it is both the slope and the absolute values of the low energy t_{10} values that are of interest for SAG/autogenous milling because these data give an indication of the ability of media particles to survive. If the trend of the t_{10} values with increasing particle size is significantly upwards, it can be inferred by extrapolation that particles in the 100 – 200 mm size range (normal media size) will not be strong enough to survive. The same argument applies if the absolute values of t_{10} at low energy are sufficiently high.

2.3.4 Density Results

As part of the standard JKTech ore property assessment procedures, the relative density of 30 randomly selected particles in the size range 26.5 mm to 31.5 mm are determined by weighing each particle, suspended initially in air and then in water.

It should be noted that this method measures the density of the particle rather than the density of the solid phase, since any internal porosity will be included in the volume measurement. A more accurate measurement of the solid phase density is possible using a Helium Pycnometer. However, it is the particle density rather than the phase density that is of concern in the assessment of SAG milling properties.

Even at the coarse particle sizes tested, it is normal to find a range of relative densities as the mineralogy of the particles varies. However, of great concern in SAG/autogenous milling is the possibility of a component in the ore that is both high density and resistant to breakage. Such material will concentrate in the load in a SAG/autogenous mill and result in higher than expected power draw.

2.4 DW TEST RESULTS

2.4.1 Summary of SAG/autogenous Mill Model Parameters

Table 1 shows the SAG/autogenous mill model parameters for Main A, Main B, No. 2 A & No. 2 B.

Table 1 - SAG/Autogenous Mill Parameters from DW Test Results

Ore Type	A	b	A * b	t_a
Main A	55.70	0.56	31.2	0.34
Main B	65.30	0.48	31.3	0.38
No. 2 A	64.00	0.63	40.3	0.28
No. 2 B	68.10	0.59	40.2	0.33

The frequency distribution of the parameters A*b and t_{10}@1kWh/t from the JKTech database of ores tested are given in Figure 1 and Figure 2 respectively.

The A*b values and the t_{10} at 1 kWh/t are given for the samples Main A, Main B, No. 2 A & No. 2 B in Table 2, which also includes figures from the JKTech database of ores tested for comparison.

Table 2 – Parameters Compared with Population of Values from Database

Ore Type	A * b			t10 @ Ecs = 1kWh/t			t_a		
	Value	Rank	%	Value	Rank	%	Value	Rank	%
Data Base Min (hardest)	12.9	1	0	7.9	1	0	0.0	1	0
Data Base Median	47.2	1,914	50	32.5	1,913	50	0.5	2,017	50
Data Base Mean	64.8	2,735	71.5	34.9	2,246	58.7	0.6	2,709	69.1
Data Base Max (softest)	809.6	3,825	100	93.6	3,825	100	6.9	3,918	100
Main A	31.2	626	16.4	23.9	547	14.3	0.34	1,103	28.2
Main B	31.3	637	16.7	24.9	669	17.5	0.38	1,430	36.5
No. 2 A	40.3	1,422	37.2	29.9	1,520	39.7	0.28	684	17.5
No. 2 B	40.2	1,403	36.7	30.4	1,591	41.6	0.33	1,038	26.5

The frequency distribution of the t_a parameter from the JKTech database of ores tested is given in Figure 3.

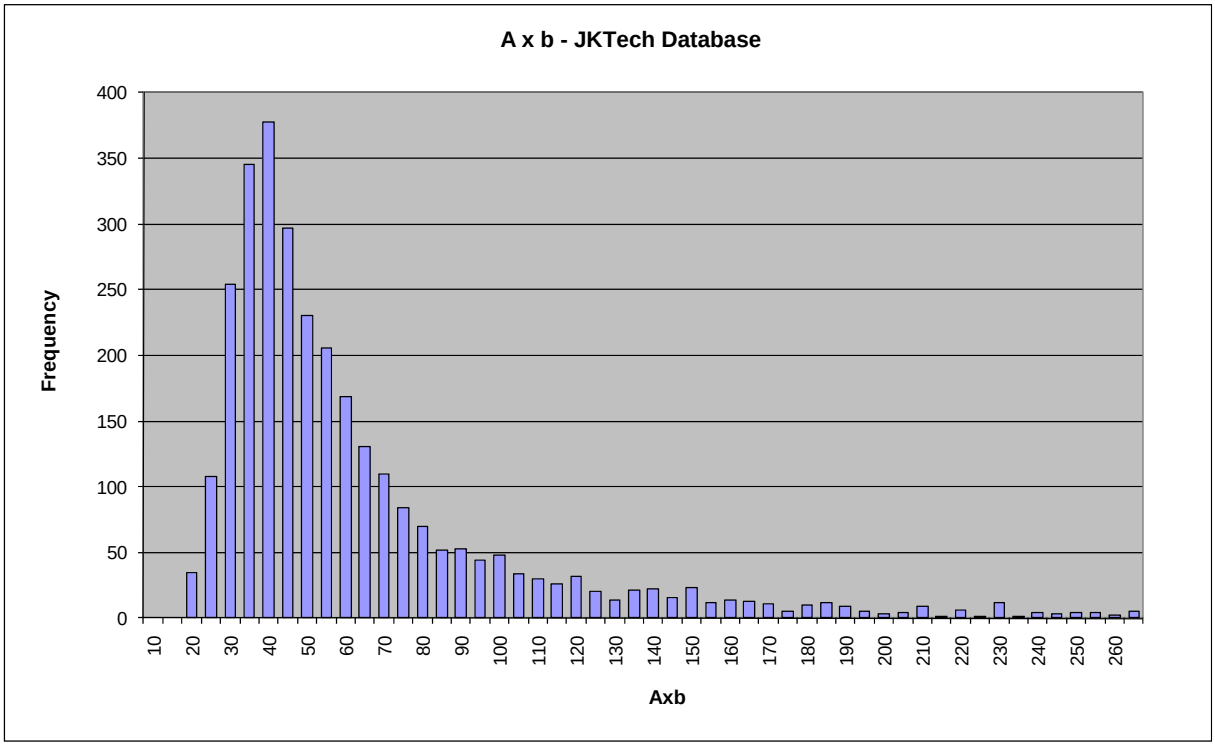

Figure 1 - Frequency Distribution of A*b in the JKTech Database

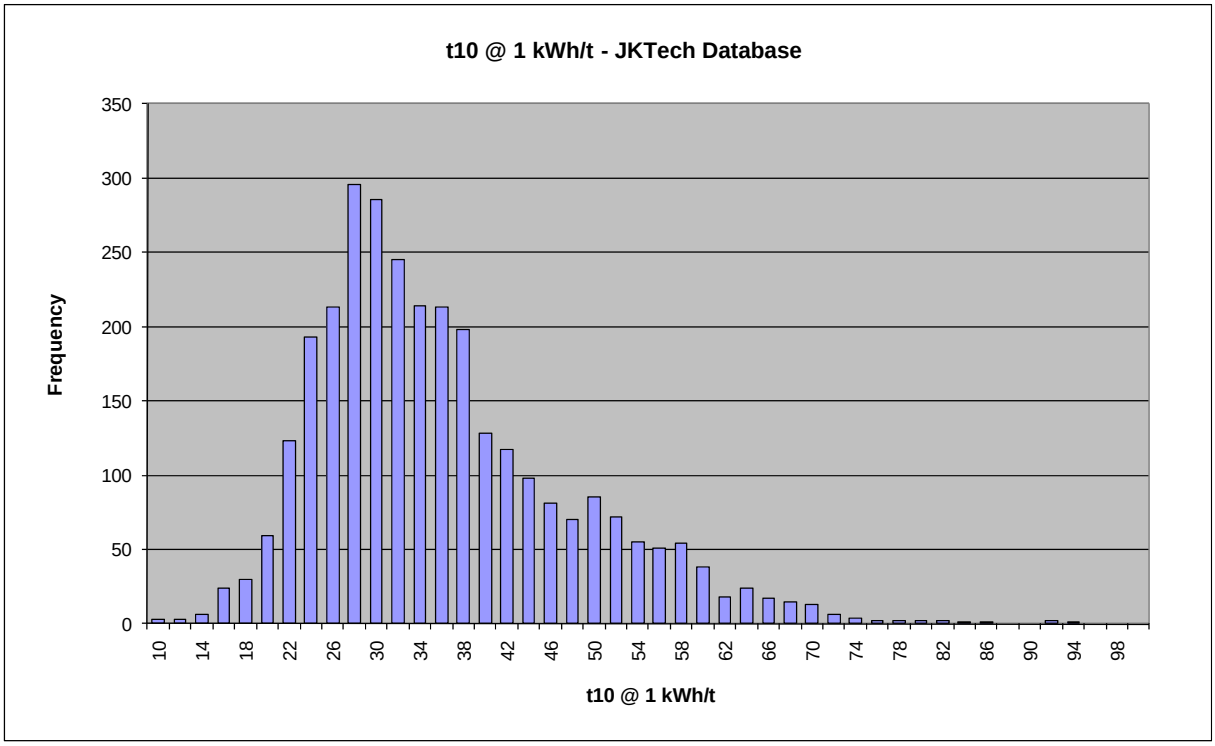

Figure 2 - Frequency Distribution of t_{10}@1kWh/t in the JKTech Database

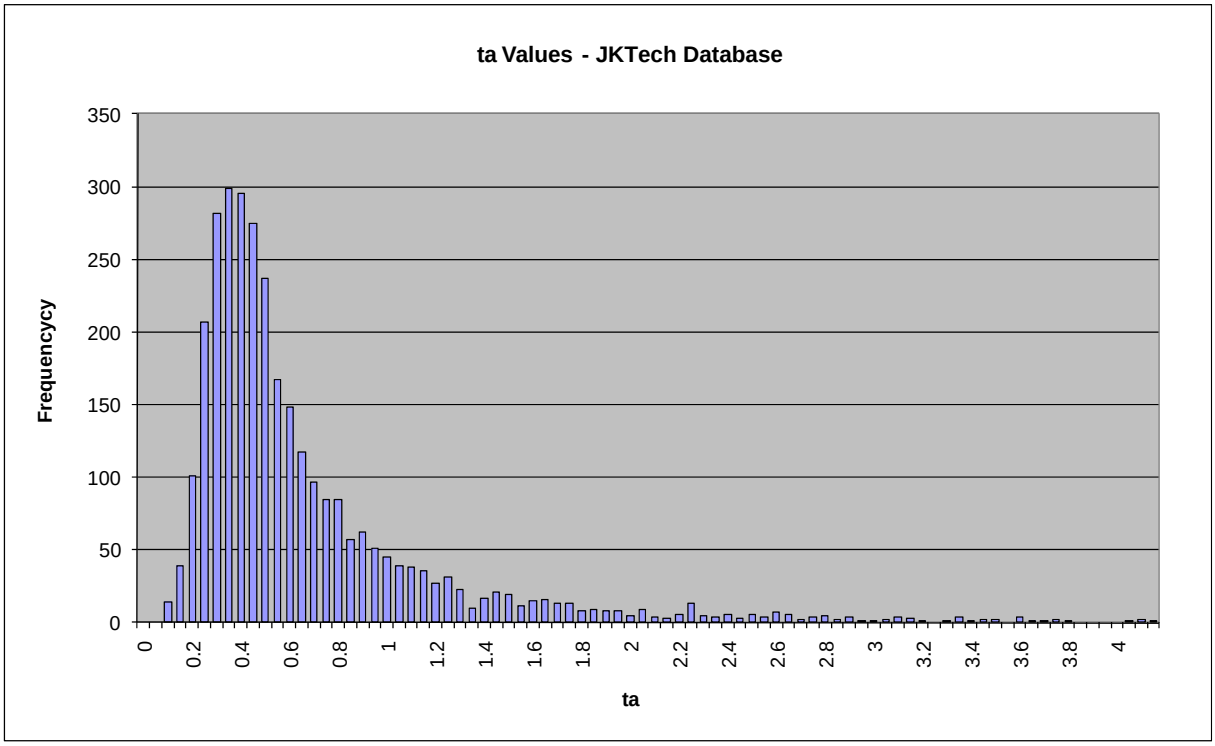

Figure 3 - Frequency Distribution of t_a in the JKTech Database

2.4.2 DW Test Results for Main A

The t_{10} versus E_{cs} relationship for sample Main A is given in Figure 4.

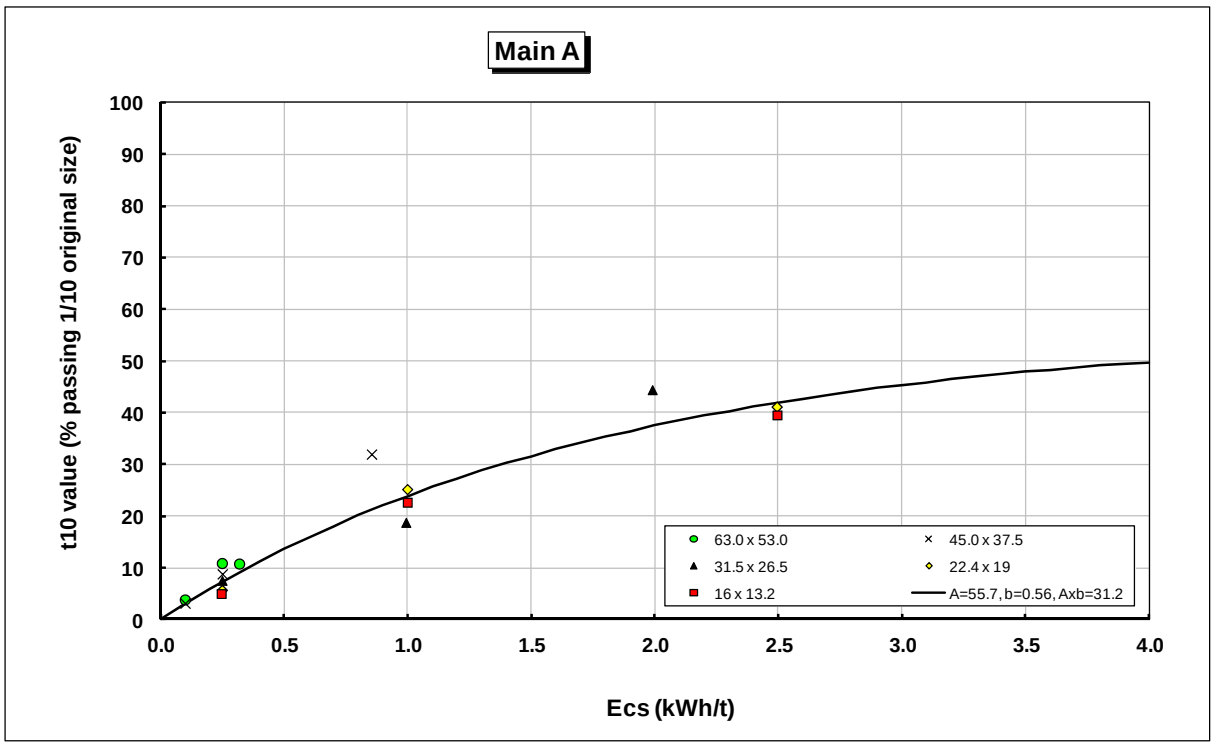

Figure 4 – t_{10}/ E_{cs} Relationships for Main A

Main A has an A*b value of 31.2, which puts this material in the hard range of resistance to impact breakage. In the JKTech database, 16.4% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.34, Main A falls into the hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 28.2% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample Main A are given in Table 3 below.

The data in Table 3 indicate that for particles of Main A of up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 3 - Crusher Model Parameters for Main A

	Size Relative to Initial Size				
	t75	**t50**	**t25**	**t4**	**t2**
t10	**cumulative percent passing**				
10.0	2.70	3.30	5.05	24.23	56.18
20.0	5.63	6.84	10.33	47.07	87.73
30.0	8.78	10.65	15.65	66.45	100.00

Specific Comminution Energy:

	Initial Particle Size, mm				
	+13.2-16.0 14.53	**+19.0-22.4 20.63**	**+26.5-31.5 28.89**	**+37.5-45.0 41.08**	**+53.0-63.0 57.78**
t_{10}	**E_{cs}, kWh/t**				
10	0.43	0.43	0.41	0.26	~~0.26~~
20	0.95	0.91	0.86	0.54	~~0.54~~
30	1.60	1.43	1.38	0.87	~~0.87~~

The Ecs values for 20.63 mm particles at t10 = 10 and 20 have been modified to avoid unrealistic extrapolation of energy requirements at lower sizes. The Ecs values for 57.78 mm particles at t10 = 10, 20 and 30 are doubtful. Values from the next finest particle size have been substituted.

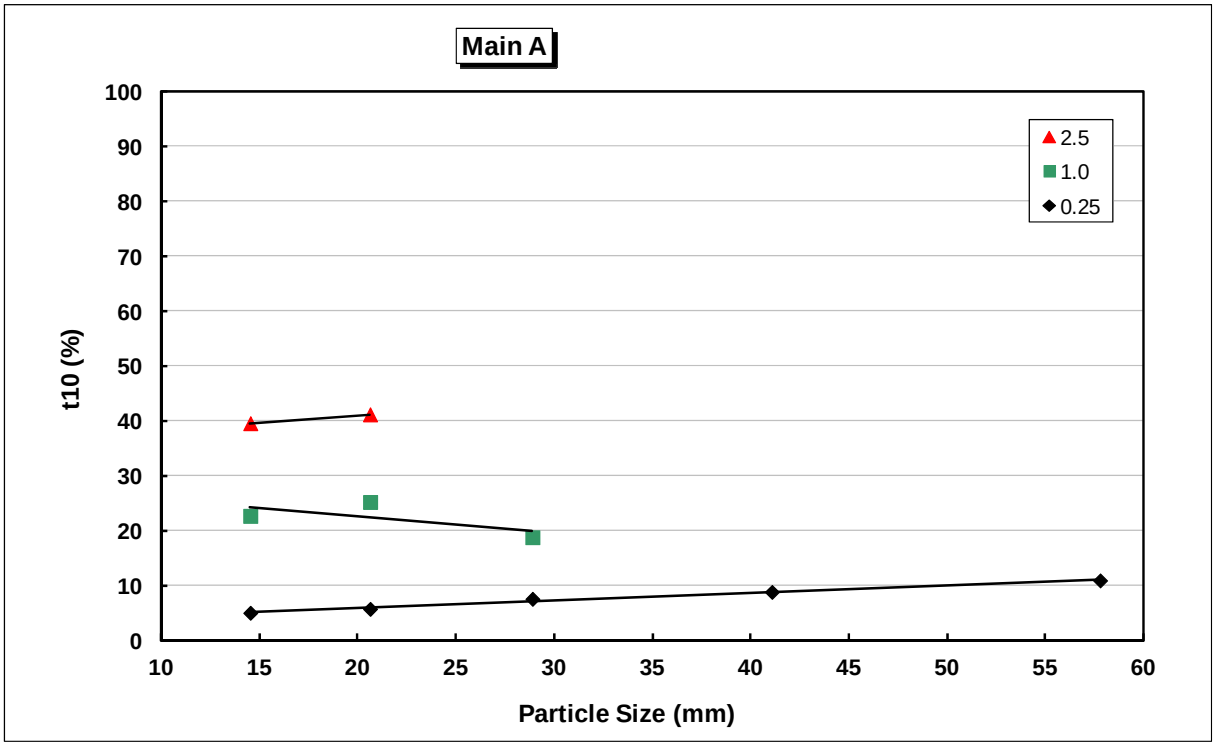

Figure 5 - Variation of Impact Resistance with Particle Size - Main A

The data graphed in Figure 5 are the t_{10} values for up to 5 different particle sizes from Main A, all broken with the very similar specific comminution energies (0.25 kWh/t, 1.0 kWh/t and 2.5 kWh/t).

The data for Main A do not follow the frequently observed trend of decreasing slope with decreasing energy (E_{cs} values).

The density measurements for the 30 particles from Main A are given in Table 4 below. These results are plotted as a histogram in Figure 6.

Table 4 - Relative Density Measurements for 30 Particles for Main A

3.45	3.57	3.27	3.28	3.67
3.35	3.38	3.38	3.42	3.60
3.35	3.67	3.81	3.51	3.75
4.10	3.55	3.43	3.50	3.27
3.29	4.19	3.42	3.32	3.61
3.38	3.36	3.49	3.68	3.93
Mean				**3.53**
Standard Deviation				**0.24**
Maximum				**4.19**
Minimum				**3.27**

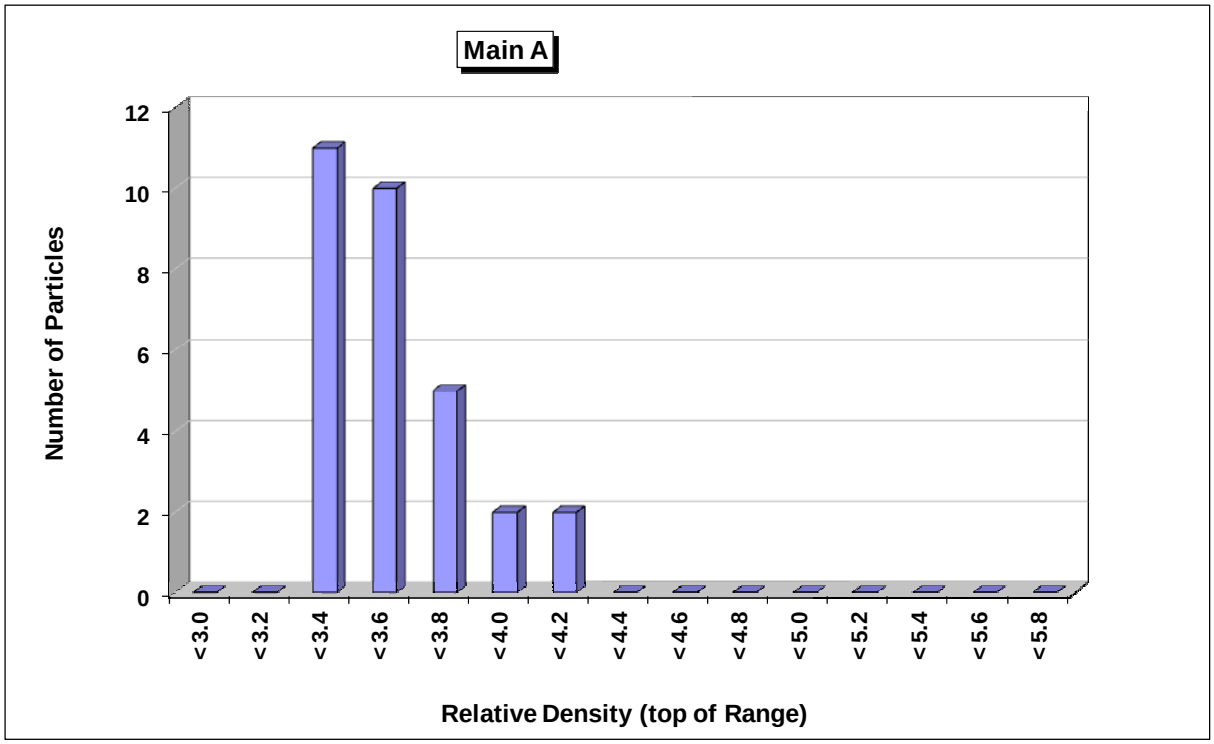

Figure 6 - Histogram of the Relative Density Measurements for 30 Particles for Main A

The Main A data contain definite evidence of bimodality in the relative density distribution, that is, definite evidence of a dense component that could concentrate in the mill load and cause power problems, resulting in a loss of throughput.

2.4.3 DW Test Results for Main B

The t_{10} versus E_{cs} relationship for sample Main B is given in Figure 7.

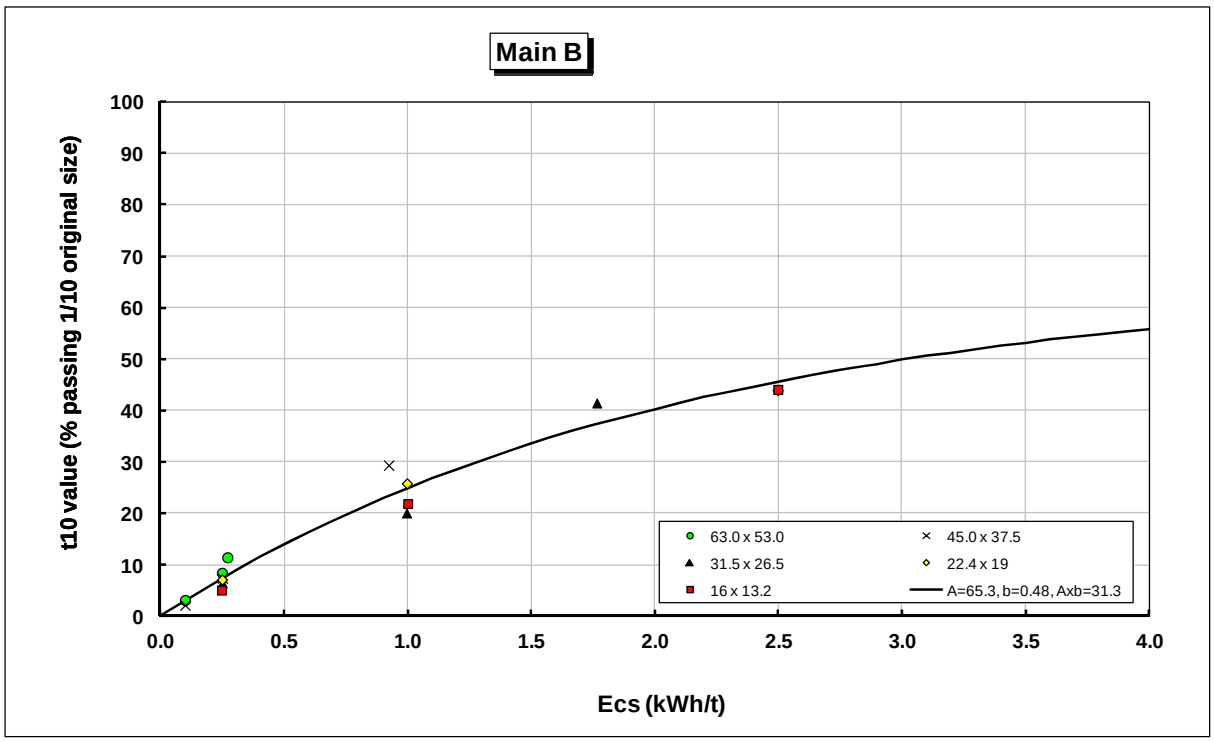

Figure 7 – t_{10}/ E_{cs} Relationships for Main B

Main B has an A*b value of 31.3, which puts this material in the hard range of resistance to impact breakage. In the JKTech database, 16.7% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.38, Main B falls into the moderately hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 36.5% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample Main B are given in Table 5 below.

The data in Table 5 indicate that for particles of Main B up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 5 - Crusher Model Parameters for Main B

	Size Relative to Initial Size				
	t_{75}	t_{50}	t_{25}	t_4	t_2
t_{10}	cumulative percent passing				
10.0	2.90	3.55	5.26	23.55	57.97
20.0	5.25	6.50	9.83	45.95	87.19

The Main B data contain definite evidence of bimodality in the relative density distribution, that is, definite evidence of a dense component that could concentrate in the mill load and cause power problems, resulting in a loss of throughput.

2.4.4 DW Test Results for No. 2 A

The t_{10} versus E_{cs} relationship for sample No. 2 A is given in Figure 10.

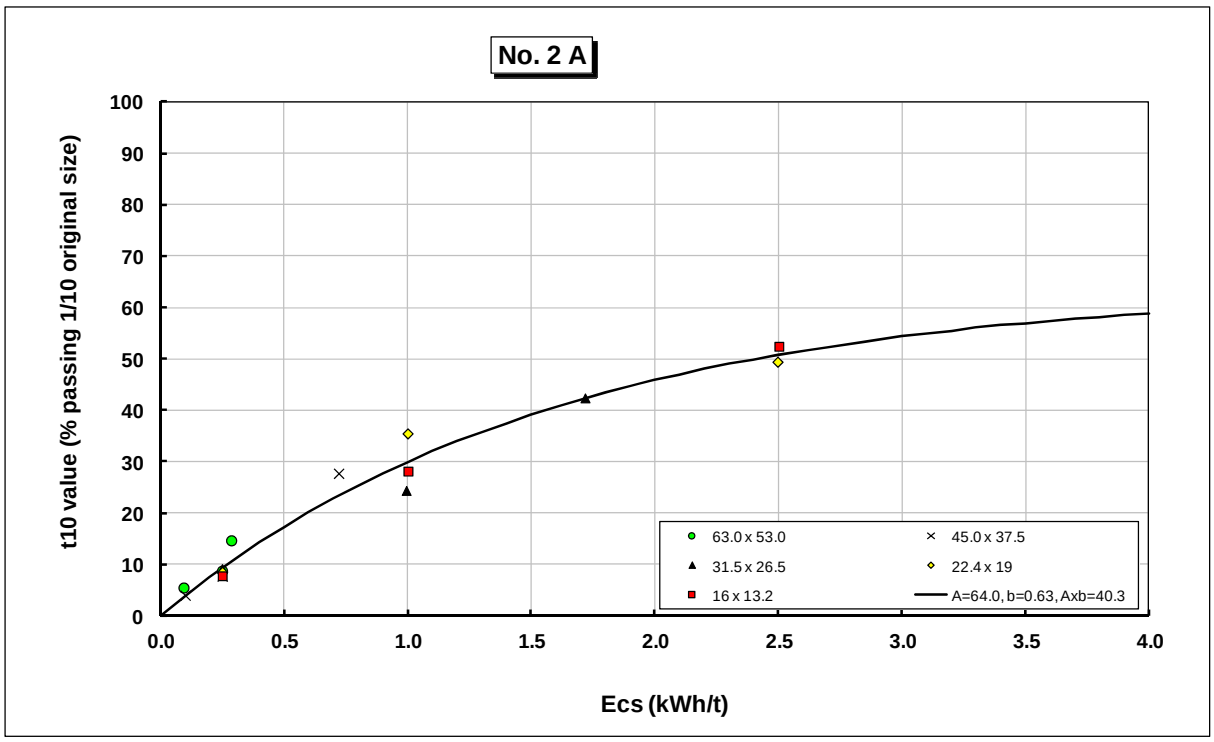

Figure 10 – t_{10}/ E_{cs} Relationships for No. 2 A

No. 2 A has an A*b value of 40.3, which puts this material in the moderately hard range of resistance to impact breakage. In the JKTech database, 37.2% of the 3,825 ore types contained in the JK database have lower A*b values (refer to Table 2).

With a t_a of 0.28, No. 2 A falls into the hard abrasion range compared with the other ore types in Table 2. In the JKTech database, 17.5% of the 3,918 ore types contained in the JK database have lower t_a values.

The crusher model parameters for sample No. 2 A are given in Table 7 below.

The data in Table 7 indicate that for particles of No. 2 A up to 63 mm, there is some increase in impact resistance with decreasing particle size.

Table 7 - Crusher Model Parameters for No. 2 A

	Size Relative to Initial Size				
	t_{75}	t_{50}	t_{25}	t_4	t_2
t_{10}	cumulative percent passing				
10.0	3.32	4.06	5.77	22.47	56.39

3 THE SMC TEST®

3.1 INTRODUCTION

The standard JK Drop-Weight test provides ore specific parameters for use in the JKSimMet Mineral Processing Simulator software. In JKSimMet, these parameters are combined with equipment details and operating conditions to analyse and/or predict SAG/autogenous mill performance. The same test procedure also provides ore type characterisation for the JKSimMet crusher model.

The SMC (SAG Mill Comminution) test was developed by Steve Morrell of SMC Testing Pty Ltd (SMCT) to provide a cost effective means of obtaining these parameters from drill core or in situations where limited quantities of material are available. The ore specific parameters have been calculated from the test results and are supplied to Venture Minerals Limited in this report as part of the standard procedure

3.2 GENERAL DESCRIPTION AND TEST BACKGROUND

The SMC Test® was originally designed for the breakage characterisation of drill core and it generates a relationship between input energy (kWh/t) and the percent of broken product passing a specified sieve size. The results are used to determine the so-called JK Drop-Weight index (DWi), which is a measure of the strength of the rock when broken under impact conditions and has the units kWh/m^3. The DWi is directly related to the JK rock breakage parameters A and b and hence can be used to estimate the values of these parameters as well as being correlated with the JK abrasion parameter - t_a. For crusher modelling the t_{10}-E_{cs} matrix can also be derived. This is done by using the size-by-size A*b values that are used in the SMC Test® data analysis (see below) to estimate the t_{10}-E_{cs} values for each of the relevant size fractions in the crusher model matrix.

For power-based calculations, (see APPENDIX C), the SMC Test® provides the comminution parameters M_{ia}, M_{ih} and M_{ic}. M_{ia} is the work index for the grinding of coarser particles (> 750 µm) in tumbling mills such as autogenous (AG), semi-autogenous (SAG), rod and ball mills. M_{ih} is the work index for the grinding in High Pressure Grinding Rolls (HPGR) and M_{ic} for size reduction in conventional crushers.

The SMC Test® is a precision test, which uses particles that are either cut from drill core using a diamond saw to achieve close size replication or else selected from crushed material so that particle mass variation is controlled within a prescribed range. The particles are then broken at a number of prescribed impact energies. The high degree of control imposed on both the size of particles and the breakage energies used, means that the test is largely free of the repeatability problems associated with tumbling-mill based tests. Such tests usually suffer from variations in feed size (which is not closely controlled) and energy input, often assumed to be constant when in reality it can be highly variable (Levin, 1989).

The relationship between the DWi and the JK rock breakage parameters makes use of the size-by-size nature of rock strength that is often apparent from the results of full JK Drop-Weight tests. The effect is illustrated in Figure 16, which plots the normalized values of A*b against particle size. This figure also shows how the gradient of these plots varies across the full range of rock types tested. In the case

of a conventional JK Drop-Weight test, these values are effectively averaged and a mean value of A and b is reported. The SMC Test® uses a single size and makes use of relationships such as that shown in Figure 16 to predict the A and b of the particle size that has the same value as the mean for a JK full Drop-Weight test.

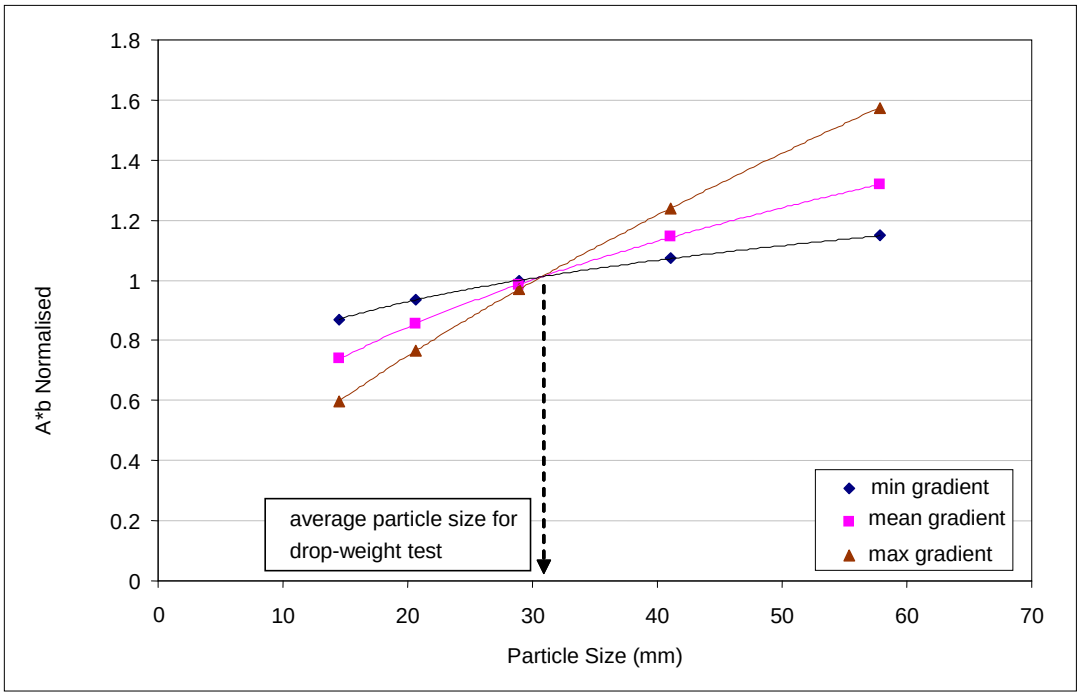

Figure 16 – Relationship between Particle Size and A*b

3.3 THE TEST PROCEDURE

In the SMC Test®, five sets of 20 particles are broken, each set at a different specific energy level, using a JK Drop-Weight tester. The breakage products are screened at a sieve size selected to provide a direct measurement of the t_{10} value.

The test calls for a prescribed target average volume for the particles, with the target being chosen to be equivalent to the mean volume of particles in one of the standard JK Drop-Weight test size fractions.

The rest height of the drop-head (gap) is recorded after breakage of each particle to allow for a correction to the drop energy. After breaking all 20 particles in a set, the broken product is sieved at an aperture size, one tenth of the original particle size. Thus, the percent passing mass gives a direct reading of the t_{10} value for breakage at that energy level.

There are two alternative methods of preparing the particle sets for breakage testing: the particle selection method and the cut core method. The particle selection method is the most commonly used as it is generally less time consuming. The cut core method requires less material, so tends to be used as a fallback method, only when necessary to cope with restricted sample availability.

3.3.1 Particle Selection Method

For the particle selection method, the test is carried out on material in one of three alternative size fractions: -31.5+26.5, -22.4+19 or -16+13.2 mm. The largest size

fraction is preferred but requires more material. The middle size fraction tends to be most commonly used, whilst the finest size fraction tends only to be used if there is an issue with starting material size distribution or quantity.

In the particle selection method, particles are chosen so that their individual masses lie within ±30% of the target mass and the mean mass for each set of 20 lies within ±10% of the target mass. A typical set of particles is shown in Figure 17.

Figure 17 – A Typical Set of Particles for Breakage (Particle Selection Method)

Before commencing breakage tests on the particles, the ore density is determined by first weighing a representative sample of particles in air and then in water.

3.3.2 Cut Core Method

The cut core method uses cut pieces of quartered (slivered) drill core. Whole core or half core can be used, but when received in this form it needs to be first quartered as a preliminary step in the procedure. Once quartered, any broken or tapered ends of the quartered lengths are cut, to square them off. Before the lengths of quartered core are cut to produce the pieces for the JK Drop-Weight testing, each one is weighed in air and then in water, to obtain a density measurement and a measure of its mass per unit length.

The size fraction targeted when the cut core method is used depends on the original core diameter. The target size fraction is selected to ensure that pieces of the correct volume will have “chunky” rather than “slabby” proportions.

Having measured the density of the core, the target volume can be translated into a target mass and with the average mass per unit length also known, an average cutting interval can be determined for the core.

Sufficient pieces of the quartered core are cut to generate 100 particles. These are then divided into the five sets of 20 and broken in the JK Drop-Weight tester at the five different energy levels. Within each set, the three possible orientations of the particles are equally represented (as far as possible, given that there are 20 particles). The orientations prescribed for testing are shown in Figure 18.

Figure 18 – Orientations of Pieces for Breakage (Cut Core Method)

The cut core method cannot be used for cores with diameters exceeding 70 mm, where the particle masses would be too large to achieve the highest prescribed energy level.

3.4 SMC TEST® RESULTS

The SMC Test® results for samples Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6 from Venture Minerals are given in Table 11. This table includes the average rock density and the JK Drop-Weight index that is the direct result of the test procedure, plus the derived estimates of parameters A, b and t_a that are required for JKSimMet comminution modelling. The values determined for the M_{ia}, M_{ih} and M_{ic} parameters developed by SMCT are also presented in this table. The M_{ia} parameter represents the coarse particle component (down to 750 µm), of the overall comminution energy and can be used together with the M_{ib} (fine particle component) to estimate the total energy requirements of a conventional comminution circuit. The use of these parameters is explained further in APPENDIX C.

In the case of the Main # 1, Main # 2, Main # 3, Main # 4, Main # 5, Main # 6, No 2 # 1, No 2 # 2, No 2 # 3, No 2 # 4, No 2 # 5 & No 2 # 6 samples from Venture Minerals,

the A and b estimates are based on the results of full drop-weight testing on similar ore (Main A, Main B, No. 2 A & No. 2 B). The full drop-weight test results were used to calibrate the DWi versus A and b correlations.

Table 11 - SMC Test® Results

Sample Designation	Calibration Sample	DWi kWh/m^3	DWi %	Mia kWh/t	Mih kWh/t	Mic kWh/t	A	b	SG	t_a
Main # 1	Main A and Main B	11.41	96	21.1	17.4	9.0	94.9	0.35	3.81	0.23
Main # 2	Main A and Main B	11.02	95	22.3	18.2	9.4	67.3	0.47	3.51	0.24

No 2 # 6	No. 2 A and No. 2 B	8.83	85	18.1	14.2	7.3	65.4	0.63	3.61	0.29

Note: For more details on how the M_{ia}, M_{ih} and M_{ic} parameters are derived and used, see APPENDIX C or go to the SMC Testing website at http://www.smctesting.com/about and click on the link to download Steve Morrell's paper on this subject.

The influence of particle size on the specific comminution energy needed to achieve a particular t_{10} value can also be inferred from the SMC Test® results. The energy requirements for three particle sizes, each crushed to three different t_{10} values, are presented in Table 12.

Table 12 – Energy Requirements Related to Particle Size

Sample Designation	Particle Size (mm)								
	14.5			28.9			57.8		
	t_{10} Values for Given Specific Energies (%)								
	10 kWh/t	20 kWh/t	30 kWh/t	10 kWh/t	20 kWh/t	30 kWh/t	10 kWh/t	20 kWh/t	30 kWh/t

The SMC Test® database now contains over 11,000 test results on samples representing more than 600 different deposits worldwide.

Around 99% of the DWi values lie in the range 0.5 to14.0 kWh/m^3, with soft ores being at the low end of this range and hard ores at the high end.

A cumulative graph of DWi values from the SMC Test® Database is shown in Figure 19 below. This graph can be used to compare the DWi of the material from Venture Minerals, with the entire population of ores in the SMCT database. The figures on the y-axis of the graph represent the percentages of all ores tested that are softer than the x-axis (DWi) value selected.

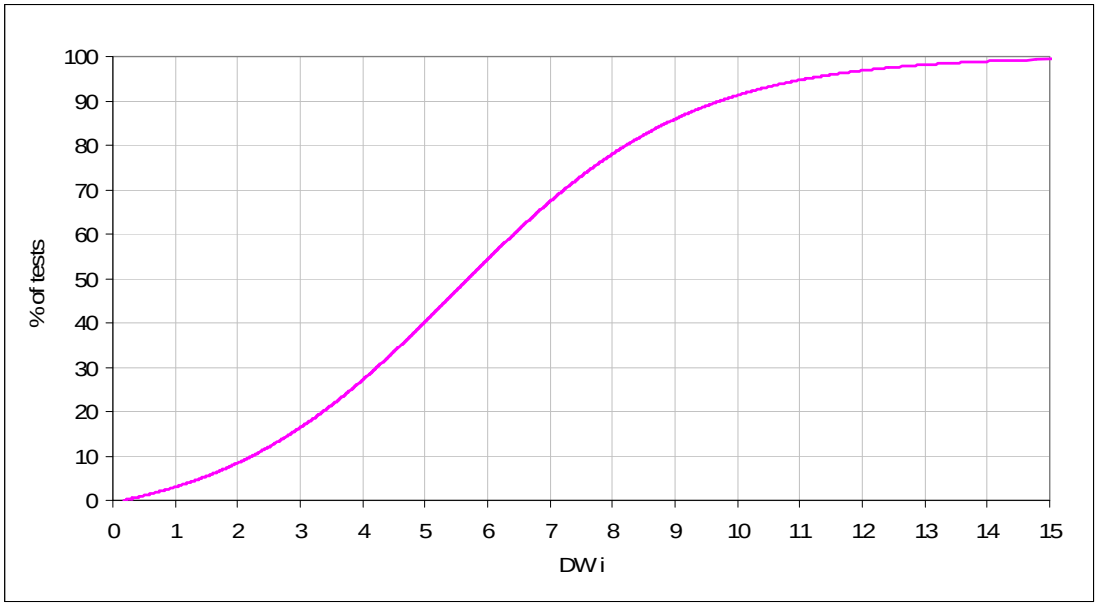

Figure 19 – Cumulative Distribution of DWi Values in SMC Test® Database

A further cumulative distribution graph is provided in Figure 20 to allow a comparison of the M_{ia}, M_{ih} and M_{ic} values obtained for the Venture Minerals material, with the entire population of values for these parameters contained in the SMCT database.

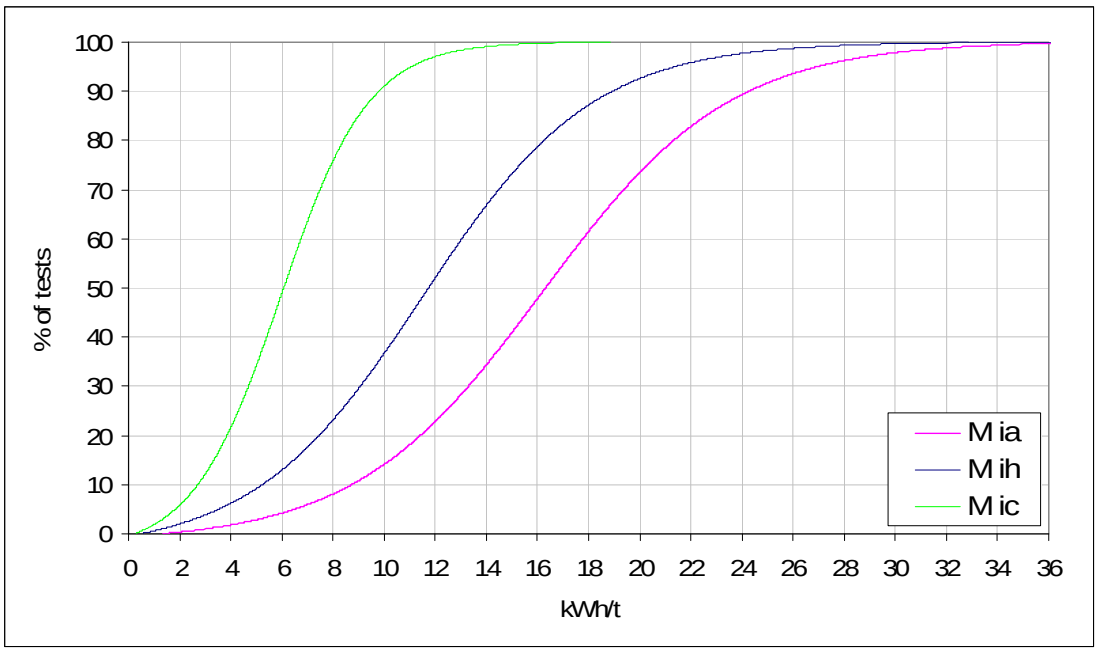

Figure 20 - Cumulative Distribution of M_{ia}, M_{ih} and M_{ic} Values in the SMCT Database

The value of A*b, which is also a measure of resistance to impact breakage, is calculated and presented in Table 13 along with indicators of how each A*b value compares with the accumulated values in the JK Drop-Weight database (from full JK Drop-Weight testing). These indicators are the Category (eg "soft" etc), the Rank (how many out of 3,825 recordings in database are harder) and the percent of database values that are harder. Note that in contrast to the DWi, a high value of A*b means that an ore is soft whilst a low value means that it is hard.

Table 13 – Derived Values for A*b and t10 at 1 kWh/t

Sample Designation	A*b				t10 @ 1 kWh/t			
	Value	Category	Rank	%	Value	Category	Rank	%
Main # 1	33.2	hard	813	21.3%	28.0	moderately hard	1196	31.3%
Main # 2	31.6	hard	658	17.2%	25.2	hard	718	18.8%
Main # 3	38.4	moderately hard	1243	32.5%	29.2	moderately hard	1385	36.2%
Main # 4	34.0	hard	867	22.7%	28.8	moderately hard	1321	34.5%
Main # 5	34.5	hard	902	23.6%	27.4	hard	1083	28.3%
Main # 6	38.4	moderately hard	1244	32.5%	28.6	moderately hard	1287	33.6%
No 2 # 1	42.8	medium	1599	41.8%	33.6	medium	2081	54.4%
No 2 # 2	33.5	hard	829	21.7%	27.2	hard	1061	27.7%
No 2 # 3	39.0	moderately hard	1302	34.0%	32.3	medium	1882	49.2%
No 2 # 4	47.7	medium	1944	50.8%	34.0	medium	2123	55.5%
No 2 # 5	40.9	moderately hard	1457	38.1%	30.9	medium	1673	43.7%
No 2 # 6	41.2	moderately hard	1476	38.6%	30.6	medium	1622	42.4%

The calculated value of t_{10} at an E_{cs} of 1 kWh/t is also shown in Table 13. This is again accompanied by Category, Rank and the percent of values in the database

that are harder, so each can be seen against the yard-stick of all other samples in the JKTech database.

The derived A*b values range from 31.6 to 47.7 giving an average of 37.9, while the t_{10} at 1 kWh/t values ranged from 25.2 to 34.0 giving an average of 29.7.

In Figure 21 and Figure 22 below, histogram style frequency distributions for the A*b values and for the t_{10} at 1 kWh/t values in the JKTech DW database are shown respectively.

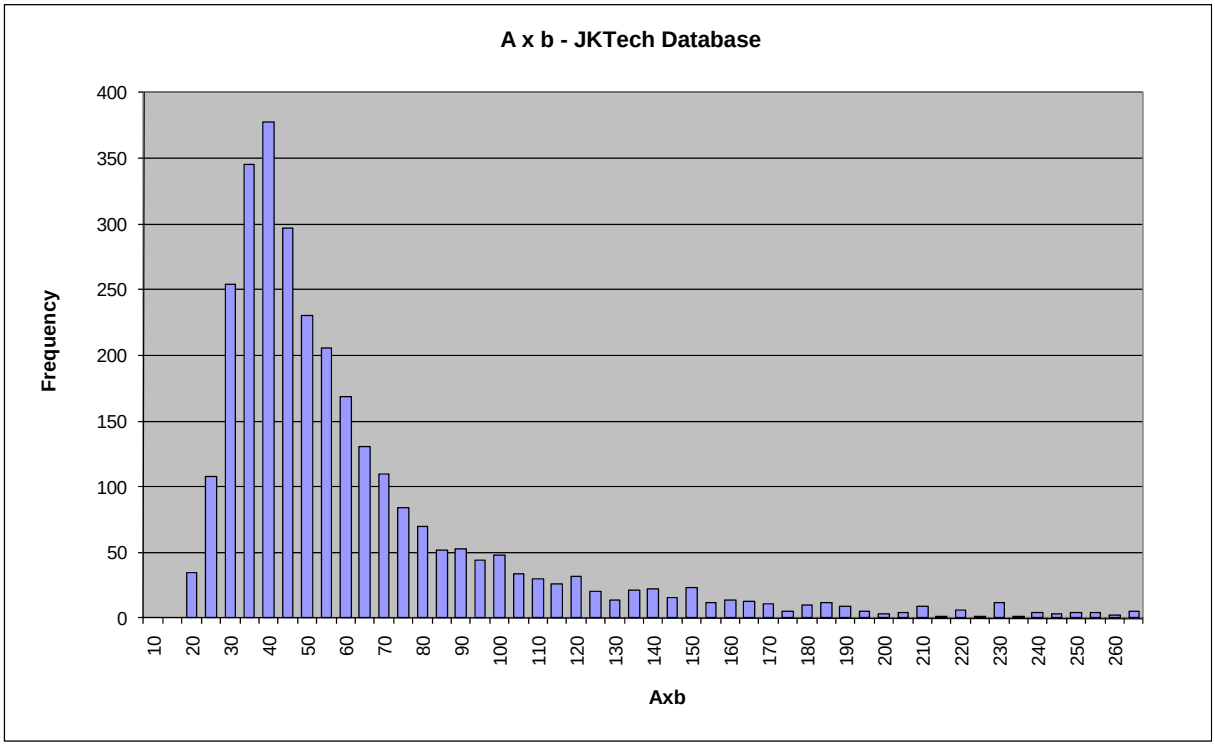

Figure 21 - Frequency Distribution of A*b in the JKTech Database

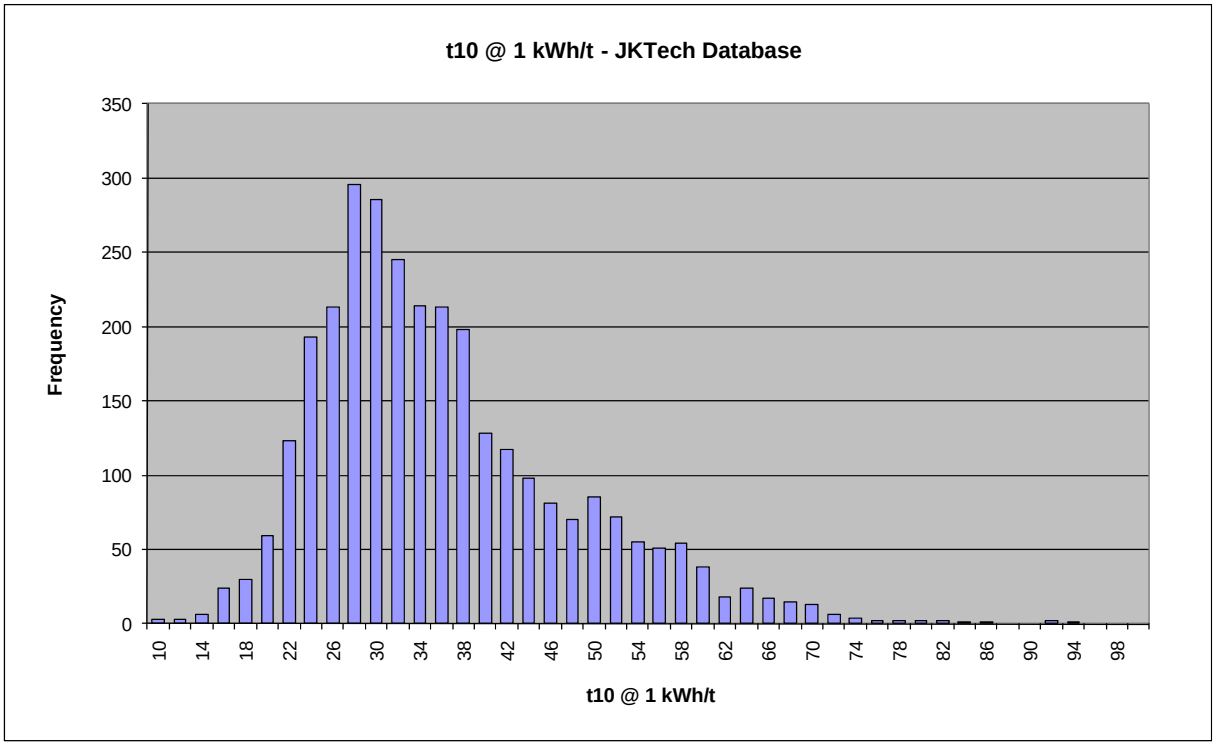

Figure 22 - Frequency Distribution of t_{10}@1kWh/t in the JKTech Database

5 DISCLAIMER

Warranty by JKTech

a. JKTech will use its best endeavours to ensure that all documentation, data, recommendations, information, advice and reports ("Material"), provided by JKTech to the client ("Recipient"), is accurate at the time of providing it.

Extent of Warranty by JKTech

b. JKTech does not make any representations as to any matter, fact or thing that is not expressly provided for in the Material.

c. JKTech does not give any warranty, nor accept any liability in connection with the Material, except to the extent, if any, required by law or specifically provided in writing by JKTech to the Recipient.

d. JKTech will not be liable to the Recipient for any claims relating to Material in any language other than in English.

e. If, apart from this Disclaimer, any warranty would be implied whether by law, custom or otherwise, that warranty is to the full extent permitted by law excluded.

f. The Recipient will promptly advise JKTech in writing of any losses, damages, compensation, liabilities, amounts, monetary and non-monetary costs and expenses ("Losses"), incurred or likely to be incurred by the Recipient or JKTech in connection with the Material, and any claims, actions, suits, demands or proceedings ("Liabilities") which the Recipient or JKTech may become liable in connection with the Material.

Indemnity and Release by the Recipient

g. The Recipient indemnifies, releases, discharges and saves harmless, JKTech against any and all Losses and Liabilities, suffered or incurred by JKTech, whether under the law of contract, tort, statutory duty or otherwise as a result of:

   i) the Recipient relying on the Material;

   ii) any liability for infringement of a third party's trade secrets, proprietary or confidential information, patents, registered designs, trademarks or names, copyright or other protected rights; and

   iii) any act or omission of JKTech, any employee, agent or permitted sub-contractor of JKTech in connection with the Material.

Limit of Liability

h. JKTech's liability to the Recipient in connection with the Material, whether under the law of contract, tort, statutory duty or otherwise, will be limited to the lesser of:

   i) the total cost of the job; or

   ii) JKTech providing amended Material rectifying the defect.

Exclusion of Consequential Loss

i. JKTech is not liable to the Recipient for any consequential, special or indirect loss (loss of revenue, loss of profits, business interruption, loss of opportunity and legal costs and disbursements), in connection with the Material whether under the law of contract, tort, statutory duty or otherwise.

Defects

j. The Recipient must notify JKTech within seven days of becoming aware of a defect in the Material. To the extent that the defect is caused by JKTech's negligence or breach of contract, JKTech may, at its discretion, rectify the defect.

Duration of Liability

k. After the expiration of one year from the date of first providing the Material to the client, JKTech will be discharged from all liability in connection with the Material. The Recipient (and persons claiming through or under the Recipient) will not be entitled to commence any action, claim or proceeding of any kind whatsoever after that date, against JKTech (or any employee of JKTech) in connection with the Material.

Contribution

l. JKTech's liability to the Recipient for any loss or damage, whether under the law of contract, tort, statutory duty or otherwise will be reduced to the extent that an act or omission of the Recipient, its employees or agents, or a third party to whom the Recipient has disclosed the Material, contributed to the loss or damage.

Severability

m. If any provision of this Disclaimer is illegal, void, invalid or unenforceable for any reason, all other provisions which are self-sustaining and capable of separate enforcement will, to the maximum extent permitted by law, be and continue to be valid and enforceable.

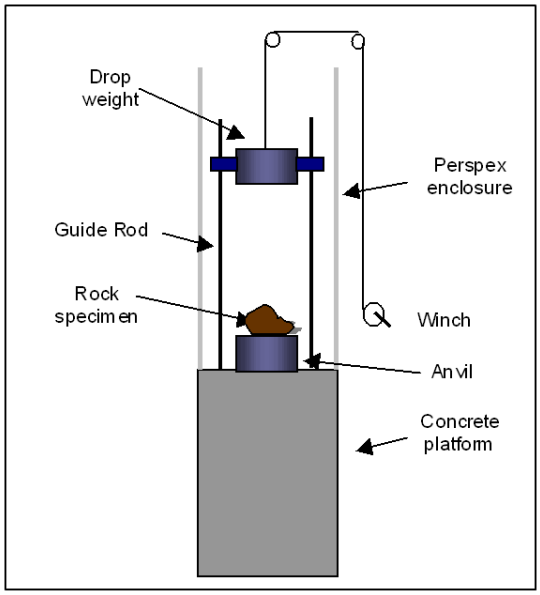
APPENDICES

APPENDIX A. BACKGROUND TO THE DROP WEIGHT TEST

A 1 INTRODUCTION

This section provides a brief description of the JK Drop-Weight test procedure.

To characterise ore breakage at different energy levels, the JKTech method uses two complimentary techniques:



1. To characterise breakage at moderate to high energy levels (i.e. impact breakage), a JK Drop-Weight device is used.

2. To characterise breakage at low energy inputs (i.e. the abrasion component of breakage), a tumbling test is used.

A 2 IMPACT BREAKAGE TESTING

The JK Drop-Weight device comprises a steel drop-weight that can be raised by a winch to a known height. A pneumatic switch releases the drop-weight, which then falls under gravity and impacts on a rock particle that is positioned on a steel anvil. The device is enclosed in Perspex shielding and incorporates a variety of features to ensure operator safety. By varying the height from which the drop-weight is released and the mass of the drop-weight, a very wide range of energy inputs can be generated. A schematic drawing of the device is given in App Figure 1.

After release, the drop-weight descends under the influence of gravity and impacts the target particle.

App Figure 1 - The JK Drop Weight Tester

The particle is broken and the drop-weight is brought to rest at a distance above the anvil approximately equal to the largest product particle. The difference in distance between the initial starting point and the final resting place of the drop-weight is used to calculate the energy that is expended in breaking the particle. Thus

$$E_i = Mg(h - x_M) \quad (1)$$

where:

E_i = energy used for breakage

M = drop-weight mass

g = gravitational constant

h = initial height of the drop-weight above the anvil

x_M = final height of the drop-weight above the anvil.

Providing the drop-weight does not rebound after impact, the application of equation (1) is valid. Where rebound occurs an additional term is required to account for the energy re-transmitted to the drop-weight. Rebound has been seen to occur only at elevated input energies. This energy will be assessed during the test work program. It is likely, however, that its magnitude will be relatively small and can be ignored with only a minimal loss in accuracy.

The assumption is made that all the energy provided is utilised in the breakage of the particle. Thus

$$E_{cs} = E_{is} = E_i / m$$

where:

E_{is} = specific input energy

E_{cs} = specific comminution energy

m = mean particle mass

To test an ore type, the original 100 kg sample is sized into selected fourth-root-of-two size fractions. Ten (10) to thirty (30) particles are required in each size fraction for each energy level, depending on particle mass. Typically fifteen (15) size/energy combinations are selected. The input energy levels for a particular test are designed to suit ore hardness but a standard set of energies are used whenever possible.

The breakage products of all particles for each size/energy combination are collected and sized. The size distribution produced is normalised with respect to the original particle size. For a wide range of energy inputs, particle sizes and ore types, the relative size distributions remain similar in shape and can be fully characterised by a single point on the distribution. The JKTech convention is to use the percentage passing one-tenth of the original particle size. This is referred to as the "t10" value.

In the manner described above, a set of t10 and Ecs values are produced for the 15 energy/size combinations.

A 3 ABRASION BREAKAGE TESTING

It is possible to characterise low energy (abrasion) breakage with a miniature drop-weight and repeated impacts. However, Leung (1987) demonstrated that a tumbling test of selected single size fractions could produce a similar result with less experimental effort.

The standard abrasion test tumbles 3 kg of -55+38 mm particles for 10 minutes at 70% critical speed in a 305 mm by 305 mm laboratory mill fitted with 4 x 6 mm lifter bars. The resulting product is then sized and the t10 value for the product is determined.

The mean particle size of the original size fraction 55 x 38 mm is 45.7 mm. The t10 size is:

1/10 x 45.7 = 4.57 mm.

A 4 USING STANDARD DW TEST RESULTS IN JKSIMMET

A 4.1 SAG/autogenous Mill Model

In the SAG/autogenous mill, both breakage mechanisms discussed in Section 2 are assumed to occur. The parameters used in the model are given in Table 1.

A 4.1.1 High Energy or Impact Breakage

To represent the impact breakage mechanism in the model, the 15 pairs of t10/Ecs data from the JK Drop-Weight test are subjected to non-linear least squares techniques to fit the following equation, which describes the relationship between breakage and impact energy:

$$t_{10} = A(1 - e^{-bE_{cs}})$$

In this equation, A and b are the fitted parameters. These parameters can then be used in the JKSimMet SAG/autogenous mill model which incorporates the same relationship.

A 4.1.2 Low Energy or Abrasion Breakage

As discussed in Section A 3, the abrasion test results in a t10 figure. The abrasion parameter used in the model, ta, is defined as

$$t_a = t_{10}/10$$

For example, if t10 = % passing 4.57 mm = 4.0%, then

$$t_a = 4.0 / 10 = 0.40$$

A 4.1.3 Combined Breakage

These two sets of parameters representing the two breakage modes are used in combination by the model to generate an ore specific appearance function. The scaling factor of 10 is applied in the calculation of ta so that the relative proportions of high and low energy breakage represented in the combined appearance function are correct.

The assumption is made that all brittle rock types break with the same general pattern and this pattern is built into the model. This assumption does not mean that the amount of energy required to achieve a particular t10 is the same for all brittle rocks. It simply means that if a single particle is broken to a particular t10 value, then the complete size distribution of the broken fragments is known.

This assumption is not perfect but is quite adequate for the purposes of the SAG/autogenous model.

To use the results of testing, the ore type parameters A and b (from JK Drop-Weight testing) and ta (from abrasion testing), are entered into the SAG/autogenous mill model in JKSimMet, together with machine dependent parameters of mill size, grate size, ball load, etc. The simulation predicts product size and mill load using appropriate breakage rates. The simulator can then also be used to predict mill performance with variations in screen and classifier configurations or even with recycle crushing.

Details of the SAG/autogenous mill model are given in Leung (1987) and Leung, Morrison, and Whiten (1987). The calculations on which the power prediction for SAG/autogenous mills is based are described in Morrell (1996).

A 4.2 Crusher Model

For the crusher model, only the high energy or impact breakage test results are used. These are presented in a somewhat different manner from the SAG/autogenous mill model.

The assumption that all brittle rocks break with the same breakage pattern is not made and the pattern for the ore under test is used. The parameters used by the crusher model are tabulated in the results section of this report. The appearance function defines the shape of the breakage distribution curve at various degrees of "broken-ness", as defined by t10. The specific comminution energy table defines the amount of energy required to achieve varying levels of "broken-ness". The form of the specific comminution energy table reflects the fact that the energy required to achieve a certain degree of breakage is sometimes found to be dependent on the initial particle size.

Details of the crusher model including power prediction are described in Andersen and Napier-Munn (1988).

A 4.3 Limitations

Experience to date demonstrates that the JK Drop-Weight test is appropriate for brittle ores over a wide range of hardness. However, it is not useful for ores which

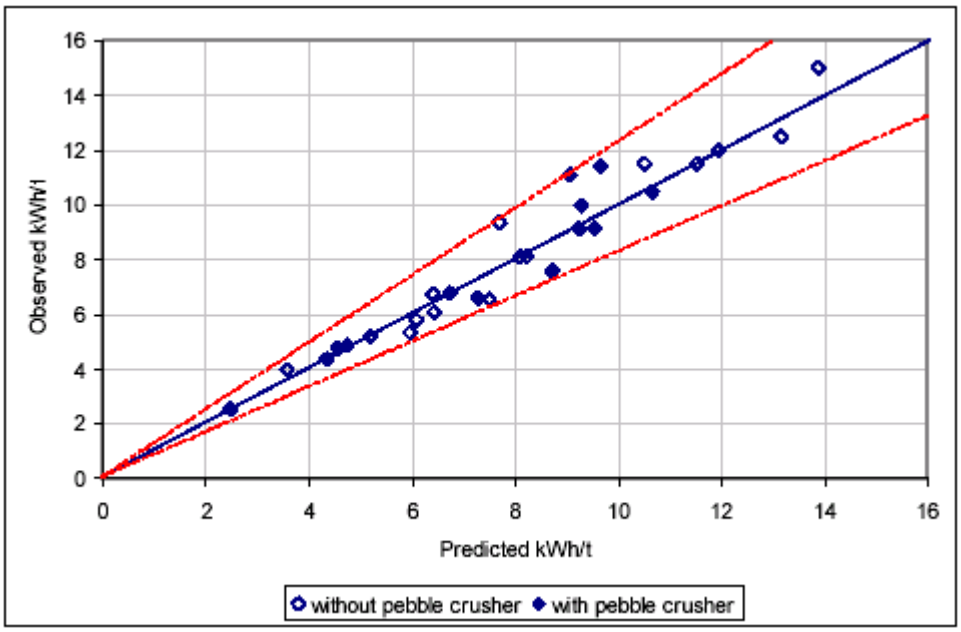
undergo plastic deformation rather than brittle fracture, such as those of high clay content.

The testing procedure is limited by the maximum particle size tested. If the ore is fractured or weaker at larger particle sizes, then JKSimMet simulations will be conservative.

For autogenous mills it is essential to have competent material in the range 150 mm to 100 mm in the feed to form the media. If autogenous milling is seriously contemplated, testing of media competency at larger particle sizes should be conducted. This can be achieved by JK Drop-Weight testing, media competency testing or full pilot plant testing.

APPENDIX B. BACKGROUND TO THE SMC TEST®

B 1 HOW THE SMC TEST® RESULTS ARE USED



The SMC Test® generates a relationship between specific input energy (kWh/t) and the percent of broken product passing a specified sieve size. The results are used to determine the JK Drop-Weight index (DWi), which is a measure of the strength of the rock when broken under impact conditions. The DWi is directly related to the JK rock breakage parameters A and b and hence can be used to estimate the values of these parameters.

Provision of a relatively low cost method of estimating the A and b parameters opens the possibility of incorporating these data into mine and mill planning operations. However a number of full JK Drop-Weight tests is still recommended for any particular orebody, to ensure that an accurate correlation between the DWi and the A and b parameters is available. The number of full JK Drop-Weight tests required for a given orebody will depend on its variability and should at least cover the major recognised ore types.

The A and b parameters are used in AG/SAG mill models, such as those in JKSimMet, for predicting how the rock will break inside the mill. From this description the models can predict what the throughput, power draw and product size distribution will be (Napier-Munn et al (1996)). Modelling also enables a detailed flowsheet to be built up of the comminution circuit response to changes in ore type. It also allows optimisation strategies to be developed to overcome any deleterious changes in circuit performance predicted from differences in ore type when such changes are indicated by the SMC Test®. These strategies can include both changes to how mills are operated (eg ball load, speed etc) and changes to feed size distribution through modification of blasting practices and primary crusher operation (mine-to-mill).

The mine to mill models require information on rock mass competence such as provided by the point load index. The DWi is correlated with the point load index and hence can also be used in blast fragmentation modelling where direct measurements of point load index are not available.

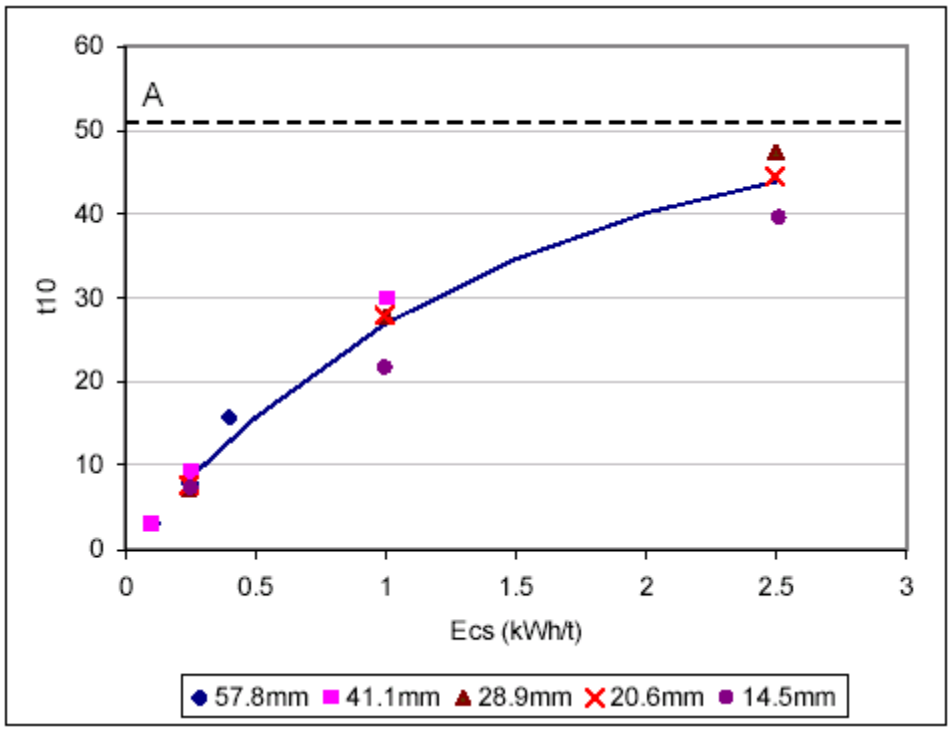
The DWi is related to the resistance of a rock to breakage under impact. SMCT has developed a series of equations that relate the DWi to the specific energy (kWh/t) requirements of complete AG and SAG mill circuits. These equations take into consideration factors such as ball charge, feed size, aspect ratio, whether the mill is operated with or without a pebble crusher and whether it is closed with a fine classifier such as a cyclone. The ability of these equations to predict AG/SAG mill circuit specific energy is illustrated in App Figure 2. The data shown cover 19 different operations and include Cu, Au, Ni and Pb/Zn ores.

App Figure 2 - Mill Power Prediction Based on DWi

It should be noted that the parameter ta, which is the parameter representing the low energy abrasion component of breakage, is not yielded by the SMC Test®. This parameter is derived from a tumbling test that is carried out as part of the full JK Drop-Weight test. The fact that it is also required as an input to the JKSimMet SAG/AG models provides a further reason for ensuring that some full JK Drop-Weight tests are also performed to represent at least the main rock types of an orebody.

B 2 IMPACT COMMINUTION THEORY

When a rock fragment is broken, the degree of breakage can be characterised by the "t10" parameter. The t10 value is the percentage of the original rock mass that passes a screen aperture one tenth of the original rock fragment size. This parameter allows the degree of breakage to be compared across different starting sizes.



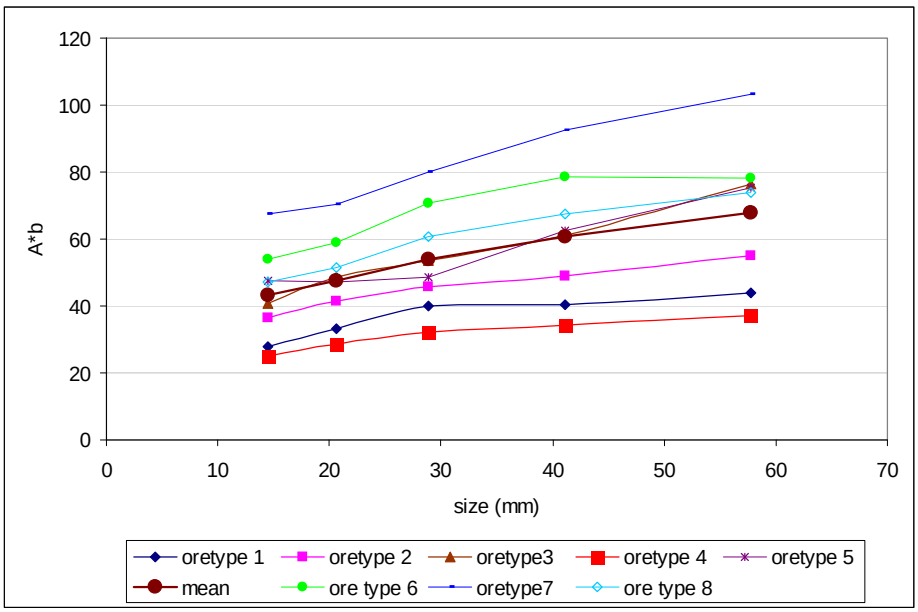
The specific comminution energy (Ecs) has the units kWh/t and is the energy applied during impact breakage. As the impact energy is varied, so does the t10 value vary in response. Higher impact energies produce higher values of t10, which of course means products with finer size distributions.

The equation describing the relationship between the t10 and Ecs is given below.

$$t_{10} = A (1 - e^{-b.Ecs})$$

As can be seen from this equation, there are two rock breakage parameters A and b that relate the t10 (size distribution index) to the applied specific energy (Ecs). These parameters are ore specific and are normally determined from a full JK Drop-Weight test.

A typical plot of t10 vs Ecs from a JK Drop-Weight test is shown in App Figure 3. The relationship is characterised by the two-parameter equation above, where t10 is the dependent variable.

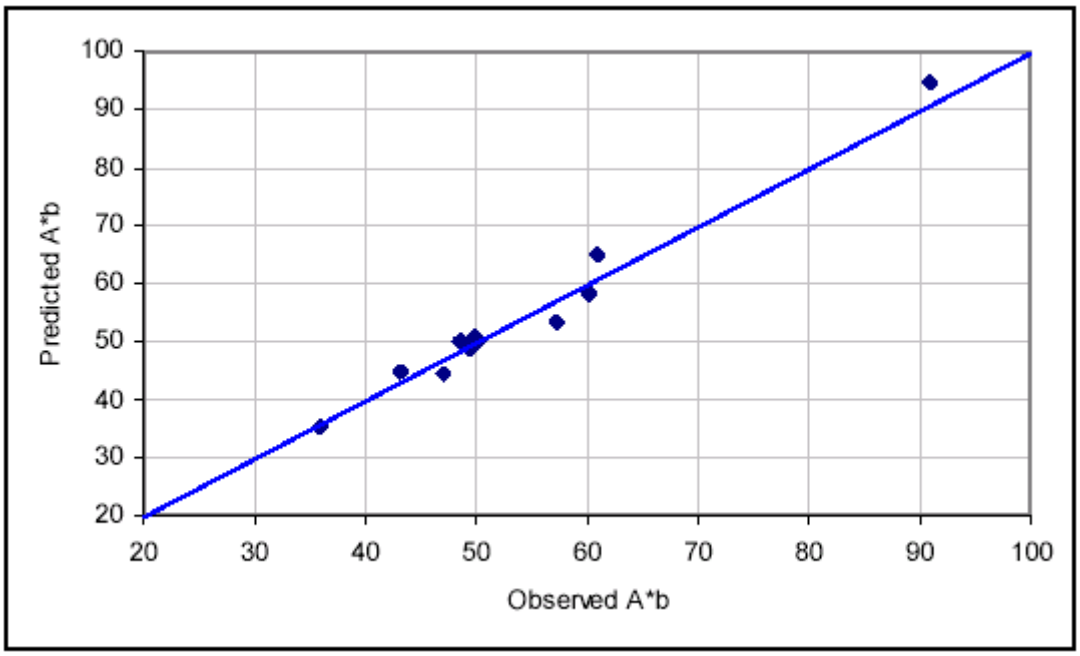


App Figure 3 - Typical t_{10} v Ecs Plot

The t10 can be thought of as a “fineness index” with larger values of t10 indicating a finer product size distribution. The value of parameter A is the limiting value of t10. This limit indicates that at higher energies, little additional size reduction occurs as the Ecs is increased beyond a certain value. A*b is the slope of the curve at ‘zero’ input energy and is generally regarded as an indication of the strength of the rock, lower values indicating a higher strength.

The A and b parameters can also be used with equation 1 to generate a table of Ecs values, given a range of t10 values. Such a table is used in crusher modelling to predict the power requirement of the crusher given a feed and a product size specification.

The DWi can be used to estimate the JK rock breakage parameters A and b by utilizing the fact that there is usually a pronounced (and ore specific) trend to decreasing rock strength with increasing particle size. This trend is illustrated in App Figure 4 which shows a plot of A*b versus particle size for a number of different rock types.



App Figure 4 - Size Dependence of A*b for a Range of Ore Types

In the case of a conventional JK Drop-Weight test these values are effectively averaged and a mean value of A and b is reported. The SMC Test® uses a single size and makes use of relationships such as that shown in App Figure 4 to predict the A and b of the particle size that has the same value as the mean for a full JK Drop-Weight test.

An example of this is illustrated in App Figure 5 - Predicted v Observed A*b

where the observed values of the product A*b are plotted against those predicted using the DWi. Each of the data points in App Figure 5 is a result from a different ore type within an orebody.

App Figure 5 - Predicted v Observed A*b

APPENDIX C. USE OF THE Mia, Mib, Mih, Mic IN PREDICTING COMMINUTION CIRCUIT SPECIFIC ENERGY

C 1 INTRODUCTION

The following technical note describes the recently extended use of the SMC Test® to include crushers and HPGRs in determining the overall specific energy demand of comminution circuits. It builds on previous work which included tumbling mills only and should be read in conjunction with an earlier technical note dated September 2007 entitled "*Use of the SMC Test® in Predicting Total Comminution Circuit Specific Energy"* as well as published papers: Morrell, 2008a, 2008b*.* This enhancement now enables the SMC Test® to be used in conjunction with the Bond ball work index test to predict the specific energy of comminution circuits where such circuits include combinations of any of the following equipment:

- AG and SAG mills
- Ball mills
- Rod mills
- Crushers
- High pressure Grinding Rolls (HPGR)

C 2 EQUATIONS

C 2.1 General

The approach divides comminution equipment into three categories:

- Tumbling mills, eg AG, SAG, rod and ball mills
- Conventional reciprocating crushers, eg jaw, gyratory and cone
- HPGRs

Tumbling mills are described using 2 indices: M_{ia} and M_{ib}

Crushers have one index: M_{ic}

HPGRs have one index: M_{ih}

For tumbling mills the 2 indices relate to "coarse" and "fine" ore properties plus an efficiency factor which represents the influence of a pebble crusher in AG/SAG mill circuits. "Coarse" in this case is defined as spanning the size range from a P_{80} of 750 µm up to the P_{80} of the product of the last stage of crushing or HPGR size reduction prior to grinding. "Fine" covers the size range from a P_{80} of 750 µm down to P_{80} sizes typically reached by conventional ball milling, ie about 45 µm. The choice of 750 µm as the division between "coarse" and "fine" particle sizes was determined during the development of the technique and was found to give the best overall results across the range of plants in SMCT's database. Implicit in the approach is that distributions are parallel and linear in log-log space.

The work index covering grinding in tumbling mills of coarse sizes is labelled M_{ia}. The work index covering grinding of fine particles is labelled M_{ib}. M_{ia} values are provided as a standard output from a SMC Test® (Morrell, 2004[a]) whilst M_{ib} values can be determined using the data generated by a conventional Bond ball mill work index test (M_{ib} is NOT the Bond ball work index). M_{ic} and M_{ih} values are also provided as a standard output from a SMC Test®.

The general size reduction equation is as follows (Morrell, 2004[b]):

$$W_i = M_i 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \qquad (1)$$

Where:

M_i = Work index related to the breakage property of an ore (kWh/tonne). For grinding from the product of the final stage of crushing to a P_{80} of 750 µm (coarse particles) the index is labelled M_{ia} and for size reduction from 750 µm to the final product P_{80} normally reached by conventional ball mills (fine particles) it is labelled M_{ib}. For conventional crushing M_{ic} is used and for HPGRs M_{ih} is used.

W_i = Specific comminution (kWh/tonne)

x_2 = 80% passing size for the product (µm)

x_1 = 80% passing size for the feed (µm)

$f(x_j)$ = $-(0.295 + x_j/1000000)$ (Morrell, 2006) (2)

For tumbling mills the specific comminution energy (Wi) relates to the power at the pinion or for gearless drives - the motor output. For HPGRs it is the energy inputted to the rolls, whilst for conventional crushers Wi relates to the specific energy as determined using the motor input power less the no-load power.

C 2.2 Specific Energy Determination for Comminution Circuits

The total specific energy (W_T) to reduce in size primary crusher product to final product is given by:

$W_T = W_a+W_b+W_c+W_h+W_s$ (3)

Where:

W_a = specific energy to grind coarser particles in tumbling mills

W_b = specific energy to grind finer particles in tumbling mills

W_c = specific energy for conventional crushing

W_h = specific energy for HPGRs

W_s = specific energy correction for size distribution

Clearly only the *W* values associated with the relevant equipment in the circuit being studied are included in equation 3.

C 2.2.1 Tumbling mills

For coarse particle grinding in tumbling mills equation 1 is written as:

$$W_a = K_1 M_{ia} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (4)$$

Where:

K_1 = 1.0 for all circuits that do not contain a recycle pebble crusher and 0.95 where circuits do have a pebble crusher

x_1 = P_{80} (µm) of the product of the last stage of crushing before grinding

x_2 = 750 µm

M_{ia} = Coarse ore work index and is provided directly by SMC Test®

For fine particle grinding equation 1 is written as:

$$W_b = M_{ib} 4\left(x_3^{\,f(x_3)} - x_2^{\,f(x_2)}\right) \quad (5)$$

Where:

x_2 = 750 µm

x_3 = P_{80} (µm) of final grind

M_{ib} = Provided by data from the standard Bond ball work index test using the following equation (Morrell, 2006):

$$M_{ib} = \frac{18.18}{P_1^{0.295}(Gbp)\left(p_{80}^{\,f(p_{80})} - f_{80}^{\,f(f_{80})}\right)} \quad (6)$$

Where:

M_{ib} = fine ore work index (kWh/tonne)

P_1 = closing screen size (µm)

Gbp = net grams of screen undersize per mill revolution

p_{80} = 80% passing size of the product (µm)

f_{80} = 80% passing size of the feed (µm)

Note that the Bond ball work index test should be carried out with a closing screen size chosen to give a final product P_{80} similar to that intended for the full-scale circuit.

C 2.2.2 Conventional Crushers

Equation 1 for conventional crushers is written as:

$$W_c = K_2 M_{ic} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (7)$$

K_2 = 1.0 for all crushers operating in closed circuit with a classifying screen. If the crusher is in open circuit, eg pebble crusher in a AG/SAG circuit, K2 takes the value of 1.19.

x_1 = P_{80} (µm) of the circuit feed

x_2 = P_{80} (µm) of the circuit product

M_{ic} = Crushing ore work index and is provided directly by SMC Test®

C 2.2.3 HPGR

Equation 1 for conventional crushers is written as:

$$W_h = K_3 M_{ih} 4\left(x_2^{\,f(x_2)} - x_1^{\,f(x_1)}\right) \quad (8)$$

K_3 = 1.0 for all HPGRs operating in closed circuit with a classifying screen. If the HPGR is in open circuit, K3 takes the value of 1.19.

x_1 = P_{80} (µm) of the circuit feed

x_2 = P_{80} (µm) of the circuit product

M_{ih} = HPGR ore work index and is provided directly by SMC Test®

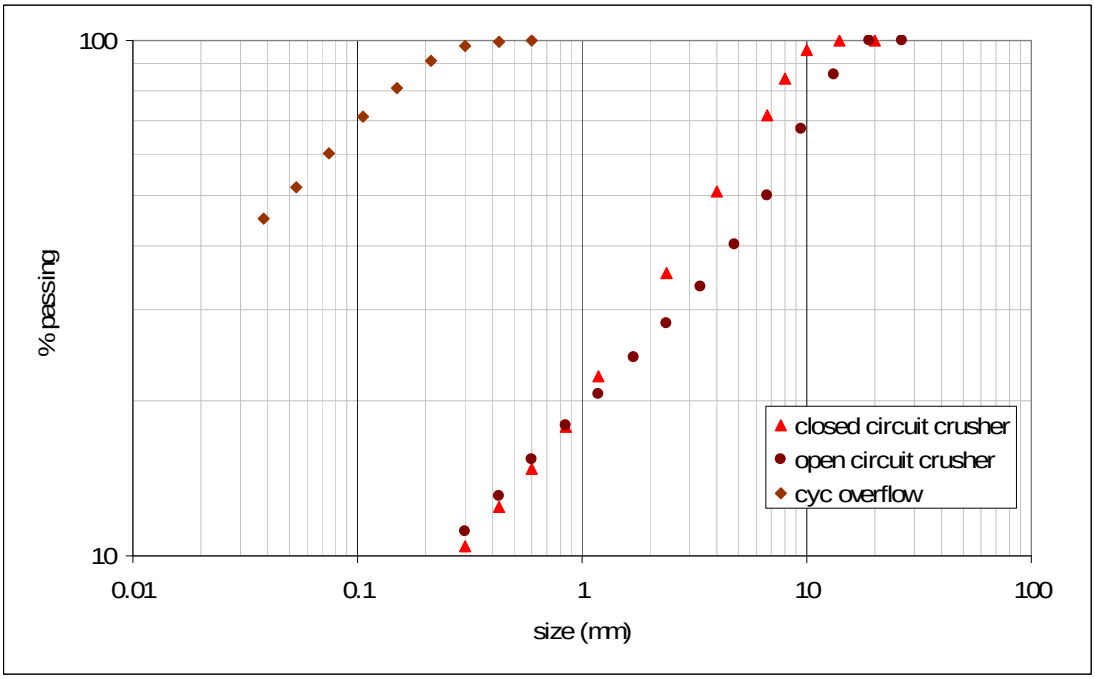
C 2.2.4 Specific Energy Correction for Size Distribution (Ws)

Implicit in the approach described in this paper is that the feed and product size distributions are parallel and linear in log-log space. Where they are not, allowances (corrections) need to be made. By and large, such corrections are most likely to be necessary (or are large enough to be warranted) when evaluating circuits in which closed circuit secondary/tertiary crushing is followed by ball milling. This is because such crushing circuits tend to produce a product size distribution which is relatively steep when compared to the ball mill circuit cyclone overflow. This is illustrated in App Figure 6, which shows measured distributions from an open and closed crusher circuit as well as a ball mill cyclone overflow. The closed circuit crusher distribution can be seen to be relatively steep compared with the open circuit crusher distribution and ball mill cyclone overflow. Also the open circuit distribution more closely follows the gradient of the cyclone overflow. If a ball mill circuit were to be fed 2 distributions, each with same P_{80} but with the open and closed circuit gradients in App Figure 6, the closed circuit distribution would require more energy to grind to the final P_{80}. How much more energy is required is difficult to determine. However, for the purposes of this approach it has been assumed that the additional specific energy for ball milling is the same as the difference in specific energy between open and closed crushing to reach the nominated ball mill feed size. This assumes that a crusher would provide this energy. However, in this situation the ball mill has to supply this energy and it has a different (higher) work index than the crusher (ie the ball mill is less energy efficient than a crusher and has to input more energy to do the same amount of size reduction). Hence from equation 7, to crush to the ball mill circuit feed size (x_2) in open circuit requires specific energy equivalent to:

$$W_c = 1.19 * M_{ic} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (9)$$

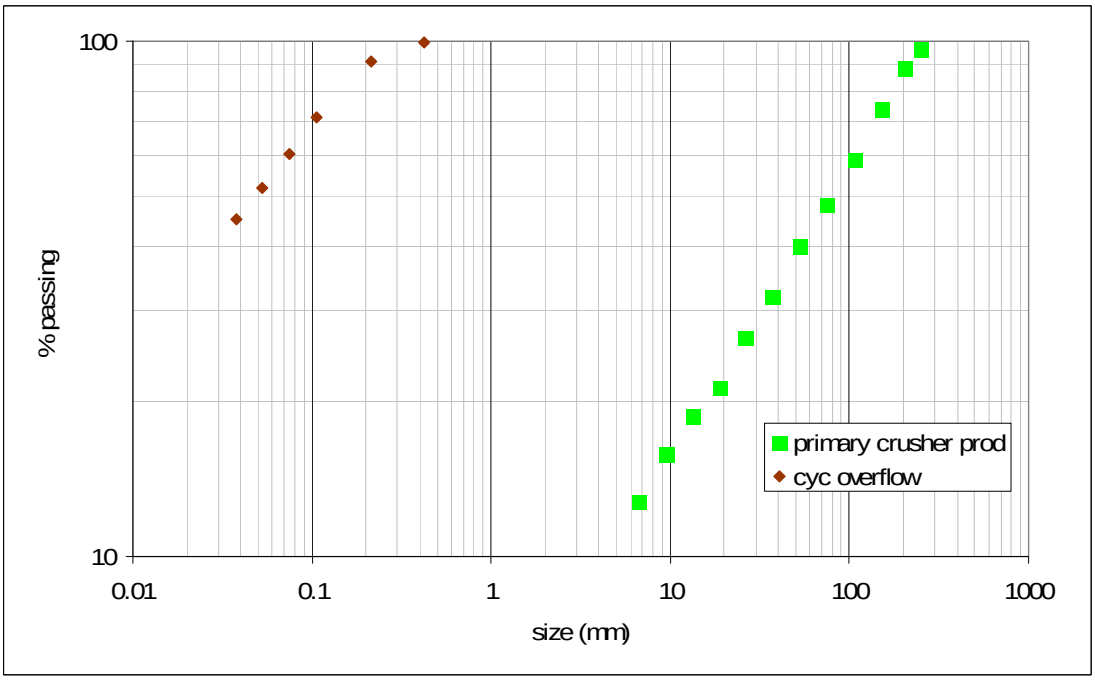
For closed circuit crushing the specific energy is:

$$W_c = 1 * M_{ic} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (10)$$



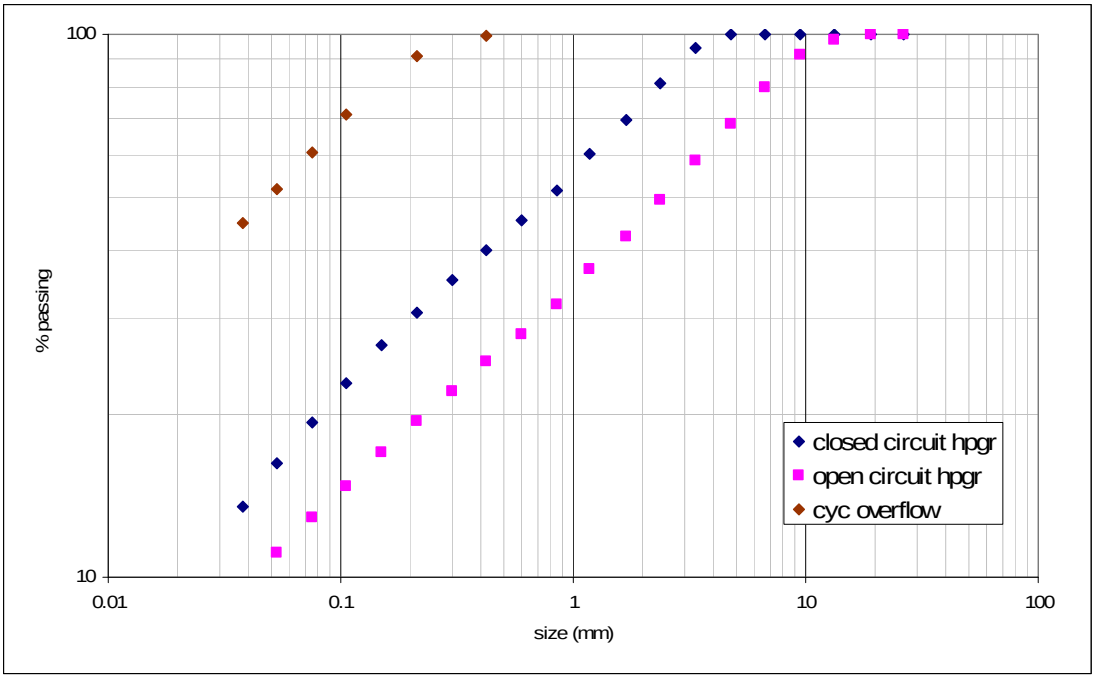
The difference between the two (eq 9 – eq 10) has to be provided by the milling circuit with an allowance for the fact that the ball mill, with its lower energy efficiency, has to provide it and not the crusher. This is what is referred to in equation 3 as W_s and for the above example is therefore represented by:

$$W_s = 0.19 * M_{ia} 4\left(x_2{}^{f(x_2)} - x_1{}^{f(x_1)}\right) \quad (11)$$



Note that in equation 11 M_{ic} has been replaced with M_{ia}, the coarse particle tumbling mill grinding work index.

In AG/SAG based circuits the need for W_s appears to be unnecessary as App Figure 7 illustrates. Primary crusher feeds often have the shape shown in App Figure 7 and this has a very similar gradient to typical ball mill cyclone overflows. A similar situation appears to apply with HPGR product size distributions, as illustrated in App Figure 8. Interestingly SMCT's data show that for HPGRs, closed circuit operation appears to require a lower specific energy to reach the same P_{80} as in open circuit, even though the distributions for open and closed circuit look to have almost identical gradients. Closer examination of the distributions in fact shows that in closed circuit the final product tends to have slightly less very fine material, which may account for the different energy requirements between the two modes of operation. It is also possible that recycled material in closed circuit is inherently weaker than new feed, as it has already passed through the HPGR previously and may have sustained micro-cracking. A reduction in the Bond ball mill work index as measured by testing HPGR products compared it to the Bond ball mill work index of HPGR feed has been noticed in many cases in the laboratory (see next section) and hence there is no reason to expect the same phenomenon would not affect the recycled HPGR screen oversize.



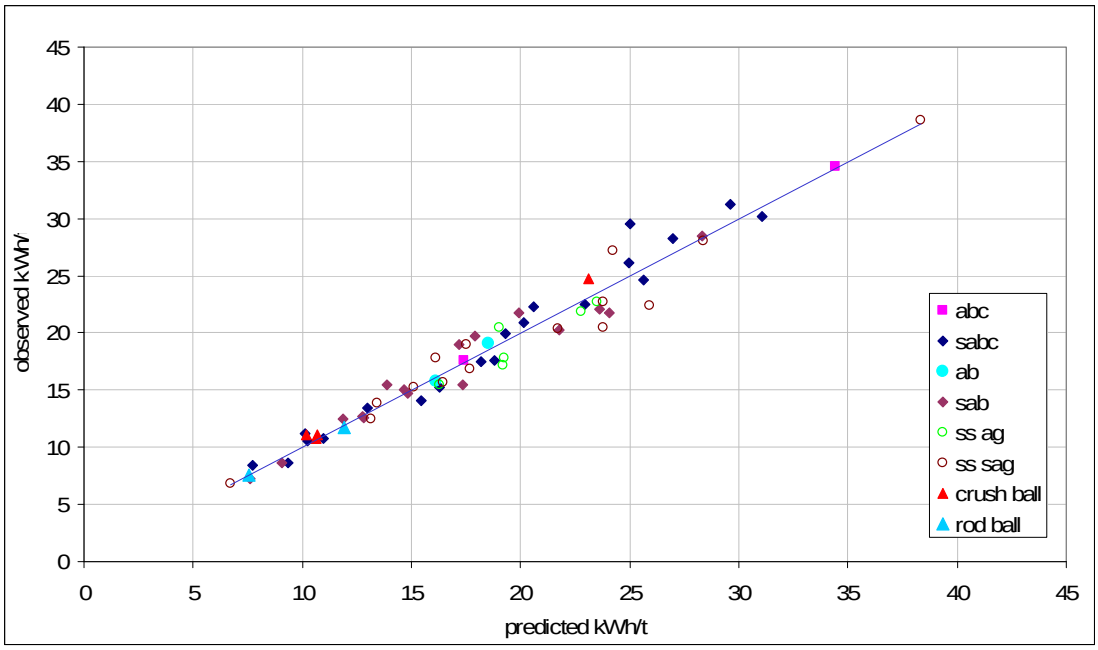
It follows from the above arguments that in HPGR circuits, which are typically fed with material from closed circuit secondary crushers, a similar feed size distribution correction should also be applied. However, as the secondary crushing circuit uses such a relatively small amount of energy compared to the rest of the circuit (as it crushes to a relatively coarse size) the magnitude of size distribution correction is very small indeed – much smaller than the error associated with the technique - and hence may be omitted in calculations.

App Figure 6 – Examples of Open and Closed Circuit Crushing Distributions Compared with a Typical Ball Mill Cyclone Overflow Distribution

App Figure 7 – Example of a Typical Primary Crusher (Open and Circuit) Product Distribution Compared with a Typical Ball Mill Cyclone Overflow Distribution

App Figure 8 – Examples of Open and Closed Circuit HPGR Distributions Compared with a Typical Ball Mill Cyclone Overflow Distribution

C 2.2.5 Weakening of HPGR Products



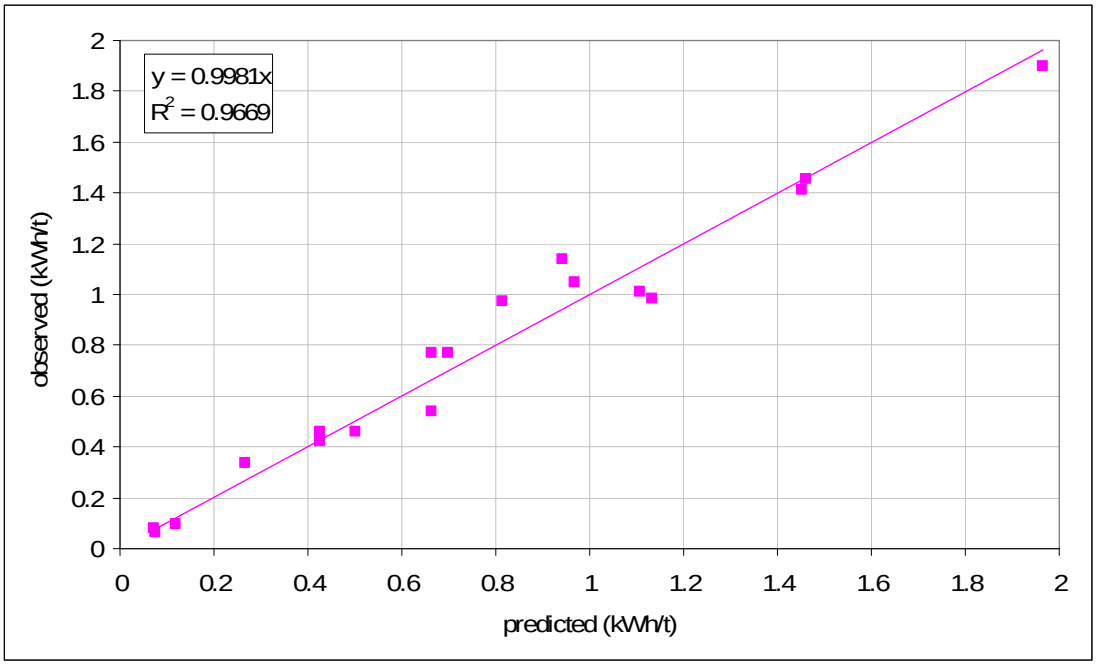
As mentioned in the previous section, laboratory experiments have been reported by various researchers in which the Bond ball work index of HPGR products is less than that of the feed. The amount of this reduction appears to vary with both material type and the pressing force used. Observed reductions in the Bond ball work index have typically been in the range 0-10%. In the approach described in this paper no allowance has been made for such weakening. However, if HPGR products are available which can be used to conduct Bond ball work index tests on then M_{ib} values obtained from such tests can be used in equation 5. Alternatively the M_{ib} values from Bond ball mill work index tests on HPGR feed material can be reduced by an amount that the user thinks is appropriate. Until more data become available from full scale HPGR/ball mill circuits it is suggested that, in the absence of Bond ball mill work index data on HPGR products, the M_{ib} results from HPGR feed material are reduced by no more than 5% to allow for the effects of micro-cracking.

C 3 VALIDATION

C 3.1 Tumbling Mill Circuits

The approach described in the previous section was applied to 65 industrial data sets. The results are shown in App Figure 9. In all cases, the specific energy relates to the tumbling mills contributing to size reduction from the product of the final stage of crushing to the final grind. Data are presented in terms of equivalent specific energy at the pinion. In determining what these values were on each of the plants in the data base it was assumed that power at the pinion was 93.5% of the measured

gross (motor input) power, this figure being typical of what is normally accepted as being reasonable to represent losses across the motor and gearbox. For gearless drives (so-called wrap-around motors) a figure of 97% was used.

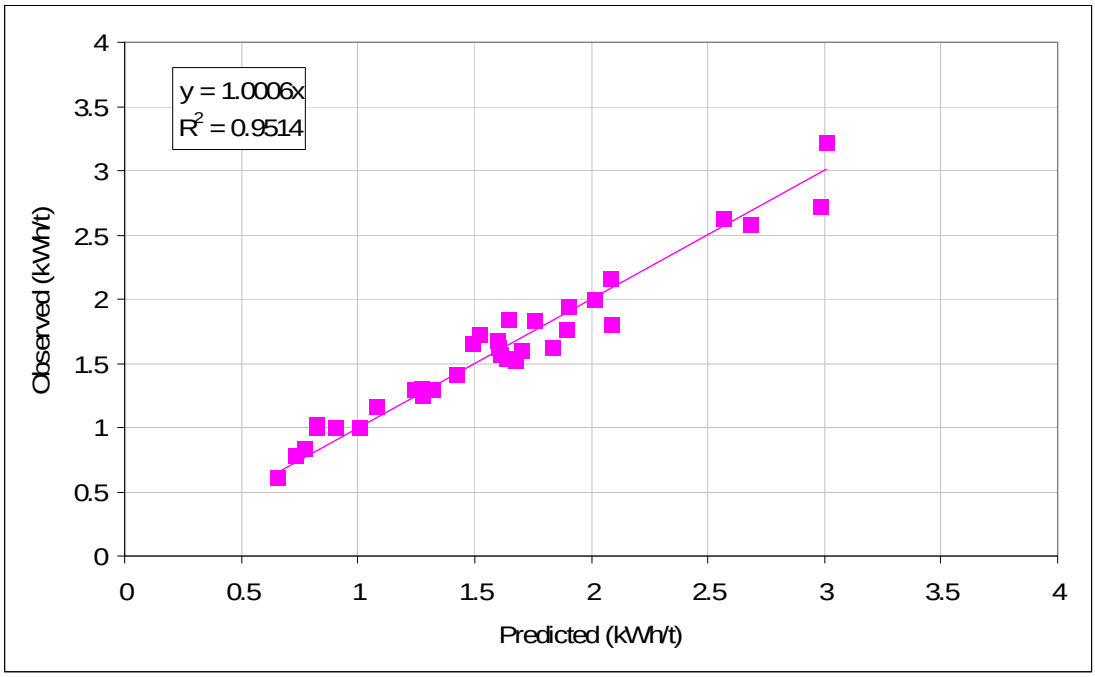


App Figure 9 – Observed vs Predicted Tumbling Mill Specific Energy

C 3.2 Conventional Crushers

Validation of equation 1 used 10 different crushing circuits (18 data sets), including secondary, tertiary and pebble crushers in AG/SAG circuits. Observed vs predicted specific energies are given in App Figure 10. The observed specific energies were calculated from the crusher throughput and the net power draw of the crusher as defined by:

Net Power = Motor Input Power – No Load Power (12)



No-load power tends to be relatively high in conventional crushers and hence net power is significantly lower than the motor input power. From examination of the 18 crusher data sets the motor input power was found to be on average 35% higher than the net power.

App Figure 10 – Observed vs Predicted Conventional Crusher Specific Energy

C 3.3 HPGRs

Validation of equation 1 for HPGRs used data from 18 different circuits (35 data sets) including laboratory, pilot and industrial scale equipment. Observed vs predicted specific energies are given in App Figure 11. The data relate to HPGRs operating with specific grinding forces typically in the range 2.5-3.5 N/mm^2. The observed specific energies relate to power delivered by the roll drive shafts. Motor input power for full scale machines is expected to be 8-10% higher.

App Figure 11 – Observed vs Predicted HPGR Specific Energy

C 4 WORKED EXAMPLES

A SMC Test® and Bond ball work index test were carried out on a representative ore sample. The following results were obtained:

SMC Test:

M_{ia} = 19.4 kWh/t

M_{ic} = 7.2 kWh/t

M_{ih} = 13.9 kWh/t

Bond test carried out with a 150 micron closing screen:

M_{ib} = 18.8 kWh/t

Three circuits are to be evaluated:

SABC

HPGR/ball mill

Conventional crushing/ball mill

The overall specific grinding energy to reduce a primary crusher product with a P_{80} of 100 mm to a final product P_{80} of 106 µm needs to be estimated.

C 4.1 SABC Circuit

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 0.95 * 19.4 * 4 * \left(750^{\ -(0.295+750/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 9.6 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8 * 4 * \left(106^{\ -(0.295+106/1000000)} - 750^{\ -(0.295+750/1000000}\right)$$

= 8.4 kWh/t

Pebble crusher specific energy

In this circuit, it is assumed that the pebble crusher feed P_{80} is 52.5mm. As a rule of thumb this value can be estimated by assuming that it is 0.75 of the nominal pebble port aperture (in this case the pebble port aperture is 70mm). The pebble crusher is set to give a product P_{80} of 12mm. The pebble crusher feed rate is expected to be 25% of new feed tph.

Combining eq 2 and 7:

$$W_c = 1.19 * 7.2 * 4 * \left(12000^{\ -(0.295+12000/1000000)} - 52500^{\ -(0.295+52500/1000000}\right)$$

= 1.12 kWh/t when expressed in terms of the crusher feed rate

= 1.12 * 0.25 kWh/t when expressed in terms of the SABC circuit new feed rate

= 0.3 kWh/t of SAG mill circuit new feed

Total net comminution specific energy:

From eq 3:

W_T = 9.6 + 8.4 + 0.3 kWh/t

= 18.3 kWh/t

C 4.2 HPGR/Ball Milling Circuit

In this circuit primary crusher product is reduced to a HPGR circuit feed P_{80} of 35 mm by closed circuit secondary crushing. The HPGR is also in closed circuit and reduces the 35 mm feed to a circuit product P_{80} of 4 mm. This is then fed to a closed circuit ball mill which takes the grind down to a P_{80} of 106 µm.

Secondary crushing specific energy

Combining eq 2 and 7:

$$W_c = 1 * 7.2 * 4 * \left(35000^{\ -(0.295+35000/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 0.6 kWh/t

HPGR specific energy

Combining eq 2 and 8:

$$W_c = 1*13.9*4*\left(4000^{\,-(0.295+4000/1000000)} - 35000^{\,-(0.295+35000/1000000)}\right)$$

= 2.9 kWh/t

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 1*19.4*4*\left(750^{\,-(0.295+750/1000000)} - 4000^{\,-(0.295+4000/1000000)}\right)$$

= 4.5 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8*4*\left(106^{\,-(0.295+106/1000000)} - 750^{\,-(0.295+750/1000000)}\right)$$

= 8.4 kWh/t

Total net comminution specific energy:

From eq 3:

W_T = 4.5 + 8.4 + 0.6 + 2.9 kWh/t

= 16.4 kWh/t

C 4.3 Conventional Crushing/Ball Milling Circuit

In this circuit primary crusher product is reduced in size to P_{80} of 6.5 mm via a secondary/tertiary crushing circuit (closed). This is then fed to a closed circuit ball mill which grinds to a P80 of 106 µm.

Secondary/tertiary crushing specific energy

Combining eq 2 and 7:

$$W_c = 1*7.2*4*\left(6500^{\,-(0.295+6500/1000000)} - 100000^{\,-(0.295+100000/1000000)}\right)$$

= 1.7 kWh/t

Coarse particle tumbling mill specific energy

Combining eq 2 and 4:

$$W_a = 1*19.4*4*\left(750^{\,-(0.295+750/1000000)} - 6500^{\,-(0.295+6500/1000000)}\right)$$

= 5.5 kWh/t

Fine particle tumbling mill specific energy

Combining eq 2 and 5:

$$W_b = 18.8 * 4 * \left(106^{\ -(0.295+106/1000000)} - 750^{\ -(0.295+750/1000000}\right)$$

= 8.4 kWh/t

Size distribution correction

$$W_s = 0.19 * 19.4 * 4 * \left(6500^{\ -(0.295+6500/1000000)} - 100000^{\ -(0.295+100000/1000000}\right)$$

= 0.9 kWh/t

Total net comminution specific energy:

From eq 3:

W_T = 5.5 + 8.4 + 1.7 + 0.9kWh/t

= 16.5 kWh/t

Preface

1. Compilation Basis

According to the contract Venture Minerals Limited of Australia and Central South University of China signed on 31st, July, 2012, Central South University has compiled the study for a plant to manufacture 4,500 tonnes per year of Chinese high quality APT from a scheelite flotation concentrate assaying in excess of 65% WO_3 from the Skarn Mine in Australia.

2. Compilation Principle

（1）Only scheelite flotation concentrate from Skarn mine in Australia is considered as raw material in the study compilation.

（2）Chinese high quality APT with high efficiency and low consumption is guaranteed after project is put into production by using the process of direct solvent extraction of tungsten from caustic leach solution of scheelite, which is the lastest and most advanced technology with environmental friendlyness and without emission of waste water.

（3）The compilation is based on systems of standard and price of Chinese market. The investment and cost are calculated in RMB.

Chapter 1 Raw Material and Product Option

The main components of scheelite flotation concentrate from Skarn Mine in Australia which is provided by Venture Minerals Limited are shown in Table 1-1.

Table 1-1 The elementary analysis for scheelite concentrate (%)

Element	Assay
WO_3	65.88
Mo	0.09
P	1.33
As	0.0048
$CaCO_3$	0.49
Bi	0.008
SiO_2	4.07
Sn	0.008
Sb	0.033
Fe	0.94
CaF_2	0.39

Process selection and metal balance calculation is based on the data of main components of scheelite concentrate from Skarn Mine in Table 1-1. As seen, the scheelite concentrate contains reasonable high contents of Si and P, the content of Mo also exceeds the limitation of Chinese quality standard for scheelite concentrate. The mass ratio of Mo/WO_3 and P/WO_3 reaches 0.14% and 2.02%, respectively. To obtain high quality of APT, the separation of Mo, P, Si and W has to be realized.

According to the requirment of Venture Minerals Limited, the scale of production of project is determined to 4,500 tonnes per year of APT. The quality of APT should meet the requirement of APT-0 class with Chinese standard of GB-10116-2007（The PDF file of GB-10116-2007 attached）.

Chapter 2 Process Selection and Demonstration

2.1 Raw material and brief review of tungsten hydrometallurgy process

2.1.1 The characteristics of raw materials

The scheelite flotation concentrate from Skarn Mine contains WO_3 of ~66% and Mo of 0.1%, which is regarded as scheelite concentrate containing high content of Si and P. To obtain high recovery of tungsten and high quality of APT product from the concentrate, the strengthening leaching and the step of separations of W-Mo and W-P/Si in process have to be employed.

2.1.2 Brief review of tungsten hydrometallurgy process

Tungsten hydrometallugy process mainly includes two steps, that is ore decomposition and pure tungsten compound preparation. The main methods in industry for ore decomposition include hydrochloric acid decomposition, sodium hydroxide leaching, soda high pressure leaching and soda sintering.

Acid decomposition is normally used to treat standard scheelite concentrate, but drawbacks of the method is large acid comsuption, poor operating environment, low metal direct recovery, and it's difficult to treat the mother liquor from acid decomposition process. Moreover, the purity of APT product generated from ammonia dissolution of H_2WO_4 cannot meet Chinese standard of APT-0 class.

Compare to the other three methods, soda sintering is suitable for treating low grade tungsten ore which contains WO_3<25%. The raw concentrate needs to be diluted with returned slag before sintering. Drawbacks of the method are low production efficiency with complicated steps, large energy consumption, low metal recovery and poor technical and economic index. So far, there has no industrial application of this method on the treatment of scheelite concentrate, except low grade ore and tungsten scraps.

Sodium hydroxide leaching method has been widely used in ore decomposition of tungsten in China, especially for wolframite decomposition. However, it is difficult to decompose scheelite unless concentrated alkali, sodium phosphate and sodium fluoride is added together. It means high cost and complicated subsequent treatment if the scheelite is decomposed by sodium hydroxide leaching method.

Soda high pressure leaching method is mature for decomposition of scheelite, as it is not only suitable for the scheelte concentrate, but also the low grade scheelite ore. The weakness of this method is high consumption of sodium carbonate and high concentrated free sodium carbonate in leach solution. When processing with the current process of ion exchange(IX) or solvent

extraction(SX) in acidic medium, it has to be considered about how to recycle soda from leach solution.

Each of the four methods on decomposition of tungsten ore discussed above has its advantages and disadvantages, industrial application should be based on the mineral characteristics and the matching process to consider.

The most commonly used methods in industry for preparing pure tungsten compounds from the caustic leach solution of tungsten ore are classical chemistry, IX and SX in acidic medium. Classical chemistry method is rarely used because of the long flowsheet, large consumption and low metal recovery. The method of IX is now widely used in China, because impurities of P, As, Si can be removed while sodium tungstate is transformed to ammonium tungstate. This method has a short process flow and simple operation, but the disadvantage is large water consumption and waste water emission, which is about 100~120 m^3/T APT. Moreover, it causes water pollution because there is large amount of NaCl, alkali and As in the waste water which cannot be recycled. Compare to the IX, the method of SX in acidic medium only can act as a transform function without any impurity removal. To remove the impurity of P, As, Si, chemical precipitation needs to be used also. Although water consumption and waste water emission is greatly reduced in this method, there is still large amount of acidic waste water containing sodium sulphate emission(30 m^3/T APT), which causes serious water environmental pollution. Furthermore, phosphorus and arsenic slag generated in the process of impurity removal is dangerous solid waste. Therefore, the current methods of IX and SX in acidic medium cannot meet the requirement of energy saving, emission reduction and clean production. Currently, the tungsten alkaline extraction process which is being popularly appliced can be used to directly extract tungsten and molybdenum from the caustic leach solution of scheelite, leaving impurities of P、As、Si in raffinate, which realizes the tungstate transformation and the impurity removal in one step. The raffinate can all be return to step of ore decomposition which saves the reagent comsumption and realizes the zero emission of waste water. The clean process for APT production from scheelite has now been successfully applied or prospectively applied in three plants of China.

2.2 Process selection and demonstration

From the discussion above, the enviroment protection and water recycling cannot meet the standard of industry admittance if the current tungsten hydrometallurgical process in China is applied as main process of pure compound production to treat scheelite concentrate from Skarn Mine in Australia for APT production. Only tungsten alkaline extraction process is recommended as main process for this project since zero emission of waste water and efficient separation of W-P and W-Si can be achieved. For

decomposition of scheelite concentrate, the soda high pressure leaching is recommended since its easy operation, high decompostion rate, low price of chemical reagent and without anticorrosive requirment of equipment. Moreover, the recycling of raffinate results in the low operation cost. Since the scheelite concentrate contains reasonably high content of P, the application of acid decomposition method will result in tungsten loss in mother liquor and lower recovery of tungsten because of the formation of phosphorus heteropoly tungstic acid. Moreover, the acidic mother liquor cannot be discharged to enviroment before treatment which costs high. Therefore, acid decompositon method cannot be used to treat the scheelite concentrate. Neither sodium hydroxide leaching or soda sintering is fit for the treatment of scheelite concentrate. In addition, the scheelite concentrate also contains reasonably high content of Mo with Mo/WO_3 mass ratio of 0.136%, but the quality standard of APT product requires Mo/WO_3 mass ratio less than 0.002%. Since the similar chemical properties of both metals, the leachings of W and Mo are quite close in the step of soda high pressure leaching, and the separation of W and Mo cannot be achieved in the step of alkaline solvent extraction. Even small amount of Mo can be separated by lowering crystallization rate of tungsten in the step of APT crystallization, the quality of APT product cannot meet the requirement of high-class APT. Hence, it is necessary to add one step of W-Mo separation in the process. In conclusion, the novel process of "soda high pressure leaching--direct SX in alkaline medium--W-Mo separation using IX--evaporation and crystallization" is recommended in this project.

In the process of alkaline solvent extraction, the leaching of WO_3 can reach 98.5% using soda high pressure leaching. Ammonium tungstate solution can be obtained from soda leach solution using SX, while the impurity of P、As、Si、F can be removed. The raffinate containing Na_2CO_3 and small amount impurity can be returned to leaching, which realizes "zero emission" of water for the process. The impurities of P、As、Si can be suppressed to be leached out by the addtion of inhibitor in leaching. But the separation of tungsten and molybdenum cannot be realized in the step of SX. The strip liquid containing ammonium tungstate and molybdate can be used to produce pure $(NH_4)_2WO_4$ solution using the patent of Central South University which is method of thiosulfate complexing and IX for the complete separation of molybdenum from ammonium tungstate. Final product of APT with high purity can be obtained by evaporation and crystallization of pure $(NH_4)_2WO_4$ solution. The product of MoS_3 with low tungsten content can be also obtained. Only $(NH_4)_2S$ and small amount of acid are added in the process of W-Mo separation, resulting in low cost and without Mo precipitation agent addition. The current method of W-Mo separtion can be also used to produce qualified APT product, but the Mo product contains high content of W and some other elements from Mo precipitation agent, resulting in low added value of Mo slag.

The technology of tungsten SX in alkaline medium has been patented by Central South University. It can be used to treat complicated scheelite for production of high quality APT. In April, 2010, a plant in Henan province of China has starded to build an industrial line to product APT from scheelite. In July, 2010, the high quality of APT product was obtained. The industrial test production has been now still in continuous and stable operation. The results demonstrate that the process of SX is practible and realiable for APT production, moreover, "zero emission" of waste water can be realized and without waste gas emission in this process. Therefore, the novel process is recommended in this project.

Although the method of MoS_3 precipitaion has widely been used in industry for separation of tungsten and molybdenum, the pH of Na_2WO_4 solution has to be adjusted to acidity from alkaline, which is fit for SX of tungsten in acidic medium. Obviously, the method is not fit for SX of tungsten in alkaline medium. Another method of selective precipitation can be also used to separate Mo from ammonium tungstate, although the final APT product can meet Chinese standard of APT-0 class, the special Mo precipitation agent with high cost is needed to be added in solution, and it is difficult to recover Mo from the obtained Mo residue. Especially, the selective precipitation method is not fit for treatment of ammonium tungstate solution with Mo/WO_3 mass ratio>1% because of high cost and difficult operation. The method of thiosulfate complexing and moving bed IX has been successfully applied in more than four industrial plants to separate Mo from ammonium tungstate solution with Mo/WO_3 mass ratio<3%, which is recommended in this project.

The process recommended for APT production not only ensures high quality product, high recovery of tungsten, and low comsumptions of reagent and energy , but also realizes "zero emission" of waste water and residue emission without containing of P、As, which is regarded as a clean and enviromental friendly process.

2.2.1 Process flowsheet

The recommended process includes main steps of roasting, high pressure leaching, SX in alkaline medium, thiosulfate complexing and IX, APT crystallization, drying and treatment of mother liquor after APT crystallization. The detailed flowsheet is shown in Figure 2-1.

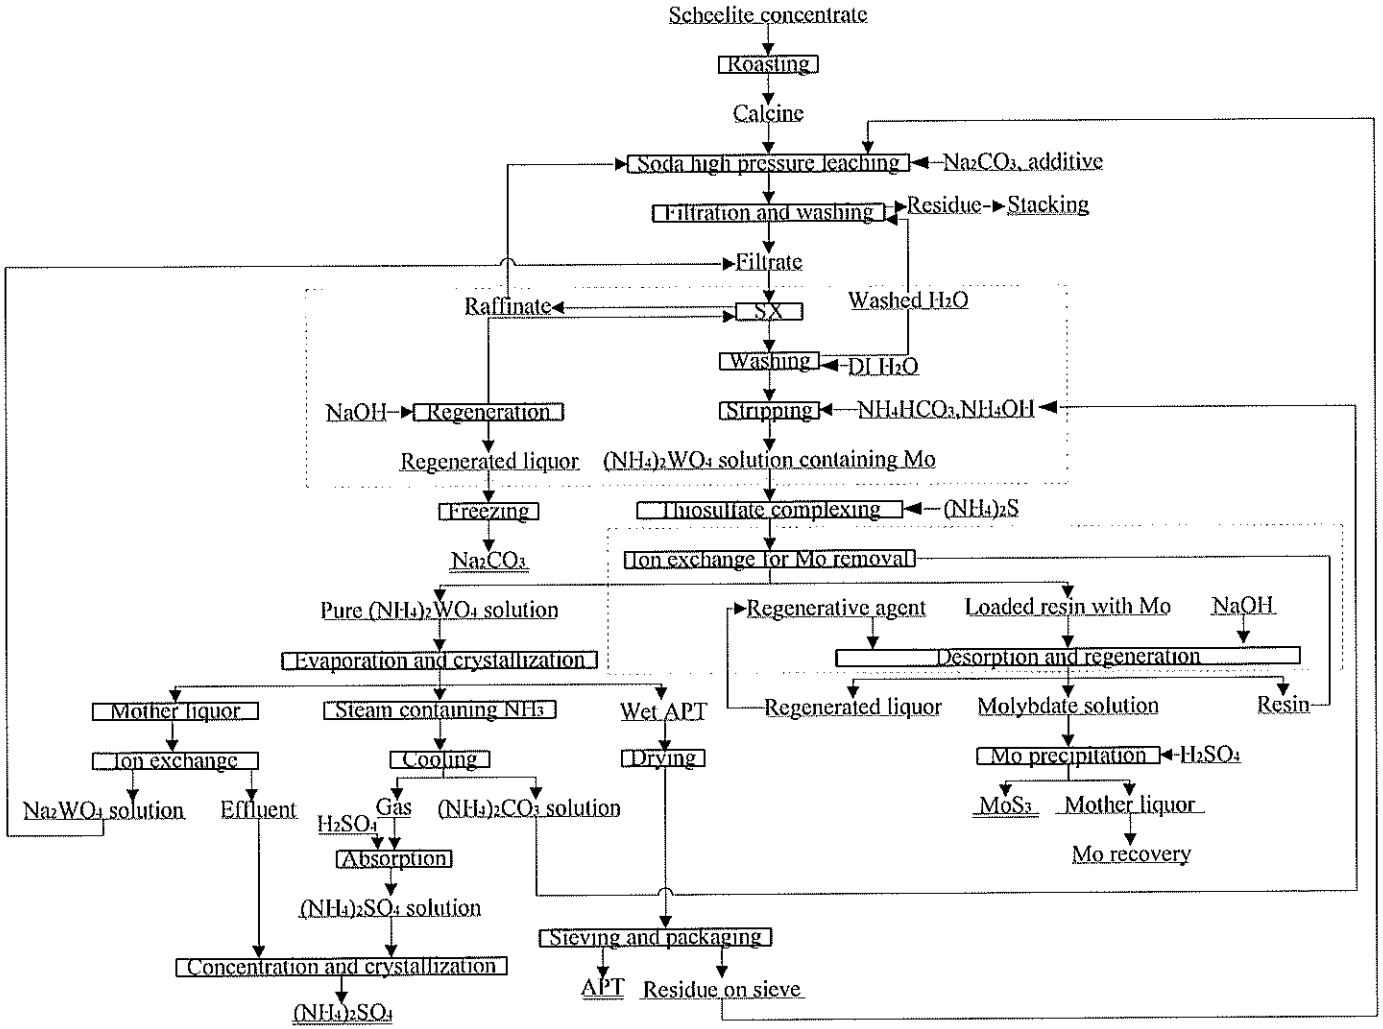

Figure 2-1 Process flowsheet for APT production from scheelite

2.2.2 Brief introduce of main steps

2.2.2.1 Roasting

The purpose of roasting is to remove flotation agent remaining in scheelite concentrate. The interference of flotation agent on follow-up hydrometallurgical process, especially on SX can thus be excluded after roasting.

2.2.2.2 Soda high pressure leaching

Soda is used to decompose scheelite concentrate using high pressure leaching of 25 atm at 220 ℃ for 2 h. Tungsten and molydbenum can be leached out as Na_2WO_4 and Na_2MoO_4, leaving P and most of gangue in residue. The main chemical reaction is as follows:

$$CaW(Mo)O_4 + Na_2CO_3 = Na_2W(Mo)O_4 + CaCO_3$$

2.2.2.3 SX in alkaline medium

Quaternary ammonium salt can be used to directly extract tungsten and molybdenum from caustic leach solution containing WO_3 of 50~70 g/L and Mo of ~0.8 g/L at ambient temperature, the sodium tungstate and molybdate can be transformed to ammonium tungstate and molybdate, while the impurity of P、As、Si、F can be removed. The raffinate can be returned to leaching step after treatment in which soda recycling can be realized. The loaded organic can be stripped using mixed solution of NH_4HCO_3 and NH_4OH followed by NaOH solution for regeneration.

The main chemical reaction can be expressed as follows:

Extraction: $Na_2W(Mo)O_4 + (R_4N)_2CO_3 = (R_4N)_2W(Mo)O_4 + Na_2CO_3$

Stripping: $(R_4N)_2W(Mo)O_4 + 2NH_4HCO_3 = 2R_4NHCO_3 + (NH_4)_2W(Mo)O_4$

Regeneration: $2R_4NHCO_3 + 2NaOH = (R_4N)_2CO_3 + Na_2CO_3 + 2H_2O$

2.2.2.4 W-Mo Separation

The separation of tungsten and molybdenum cannot be realized in the step of SX. The strip liquor contains ammonium tungstate and molybdate, in which the mass ratio of Mo/WO_3 reaches about 0.136%. To obtain high purity product of APT, it is necessary to completely remove molybdenum from ammonium tungstate solution. The method of thiosulfate complexing---IX is recommended for Mo removal in this project.

The H_2S gas or $(NH_4)_2S$ solution is added into ammonium tungstate solution containing molybdenum. MoO_4^{2-} reacts with S^{2-} to form complex:

$$(NH_4)_2MoO_4 + 4(NH_4)_2S = (NH_4)_2MoS_4 + 4NH_4OH + 4NH_3$$

After thiosulfate complexing, the solution is passed through moving-bed column equipped with special IX resins, molybdenum can be adsorbed:

$$RCl + MoS_4^{2-} = R_2MoS_4 + 2Cl^-$$

Tungsten can also be adsorbed by the resin, but it can be replaced by MoS_4^{2-}

since the affinity of MoS_4^{2-} on resin is larger than that of WO_4^{2-}.

$$RCl + WO_4^{2-} = R_2WO_4 + 2Cl^-$$
$$R_2WO_4 + MoS_4^{2-} = R_2MoS_4 + WO_4^{2-}$$

The loaded resin with MoS_4^{2-} can be stripped using NaOH solution followed by acid for regeneration and reuse.

$$R_2MoS_4 + NaOH = ROH + Na_2MoS_4$$
$$ROH + HCl = RCl + H_2O$$

To obtain pure ammonium tungstate soluton, moving bed technology has to be employed to ensure the stability of resin layer and chromatographic separation.

After pH adjustment of the strip liquor containing Na_2MoS_4 to 2~2.5, molybdenum can be precipitated as MoS_3. After filtration, the residue containing >30% Mo can be obtained. Small amount of tungsten in strip liquor can be returned to the step of tungsten recovery from mother liquor.

$$Na_2MoS_4 + 2HCl = MoS_3 + 2NaCl + H_2S$$

2.2.2,5 APT Crystallization

The pure ammonium tungstate solution is evaporated in the reaction kettle with intermittent operation at 90~100 ℃ to remove ammonia and to obtain APT crystal. The main chemical reaction is shown as follows:

$$12(NH_4)_2WO_4 = 5(NH_4)_2O \cdot 12WO_3 \cdot 5H_2O + 14NH_3\uparrow + 2H_2O\uparrow$$

2.2.2.6 Tungsten recovery from mother liquor after APT crystallization

The ammonium tungstate solution after Mo removal is acidified using H_2SO_4 to adjust pH to 3~4 , the macroporous weakly basic resin is then used to adsorb tungsten from acidified solution using fixed bed IX column. The loaded resin can be stripped using NaOH solution. The resultant solution containing Na_2WO_4 can be sent to the step of SX and the stripped resin can be reused after regeneration using H_2SO_4. The main chemical reactions are expressed as follows:

Acidification: $12(NH_4)_2WO_4 + 18H^+ = (NH_4)_6H_2W_{12}O_{40} + 18NH_4^+ + 8H_2O$

Adsorption: $3(R_3NH)_2SO_4 + H_2W_{12}O_{40}^{6-} = (R_3NH)_6H_2W_{12}O_{40} + 3SO_4^{2-}$

Desorption: $(R_3NH)_6H_2W_{12}O_{40} + 24OH^- = 12WO_4^{2-} + 6R_3N + 16H_2O$

Regeneration: $R_3N + H_2SO_4 = (R_3NH)_2SO_4$

2.2.2.7 Drying and sieving of APT

The wet APT crystal from evaporation is dried using microwave dryer and then sieved using vibration sieve to obtain qualified APT product.

2.2.3 Characteristics of recommended process

The advantages of recommended process for the production of Chinese

standard APT-0 class product are as follows:

（1）The process of high pressure leaching with soda followed by SX is employed to produce high standard of APT with high tungsten recovery, low chemical reagent consumption and environmental friendlyness. This process lays the foundation for realizing "zero emission" of waste water, in which soda can be recycled.

（2）The method of thiosulfate complexing--IX is employed to completely separate molybdenum from tungsten with low tungsten loss, low operation cost and without molybdenum precipitation reagent addtion. The final APT product with high quality can be obtained.

（3）High comprehensive utilization of resources. As well as obtaining high quality APT, molybdenum can be also recovered from scheelite concentrate and sold as molybdenum concentrate.

（4）Given full consideration of environment protection and water recycling, the whole process generates small amount of three wastes which can be discharged after simple treatment. In particular, "zero emission" of water can be almost achieved.

Chapter 3 Technical and economic index and material balance

3.1 Technical and economic index

The main components of scheelite concentrate are shown in Table 1-1.
Product and annual output: 4,500 tonnes APT per year
Product quality: meets Chinese standard of GB/T10116-2007(attached)
Annual production time: 320 days
Metal recovey in each step is listed in Table 3-1.

Table 3-1 Metal recovey in each step of whole process

No	Step	Tungsten loss (%)		Molybdenum loss (%)		Direct recovery	
		unreturnable	returnable	unreturnable	returnable	WO_3	Mo
1	Roasting	0.2	0	0.2	0	99.8	99.8
2	leaching	2.0	0	2.0	0	98.0	98.0
3	SX	0.5	2.0	0.5	2.0	97.5	97.5
4	W-Mo separation	0.5	0	0.5	0	99.5	99.5
5	APT evaporation	0.1	4.9	0	0	95.0	100.0
6	APT Dry and Sieving	0.2	0.8	0	0	99.0	100.0
7	Mother liquor treatment	2.0	0	0	0	98.0	100.0
Total recovery						**96.3**	**95.5**

3.2 Material balance

Metal balance in each step calculated on basis of content of WO_3 in APT-0 class (GB/T10116-2007, APT-0 class) of 88.5% is shown in Table 3-2.

Table 3-2 Metal balance of APT production day and night

No	Step	Input							Output						
		No	Material	Amount (Kg)				Remarks	No	Material	Amount (Kg)				Remarks

Chapter 4 Production equipment selection and demonstration

4.1 Selection principle

On the premise of ensuring production scale and product quality, the selection of equipment follows the principle of:

（1）Progressiveness, realibity, economy

（2）Meet requirment of technical index, ensuring high quality of product. Advanced and mature equipment in China is priority selection.

（3）Good corrosion resistance for ensuing the final product without pollution and the equipment service life.

（4）Good sealing performance for improvement of labor conditions and protection of environment.

（5）Mechanical automation for easy operation.

4.2 Main equipment selection

4.2.1 Roasting furnace

Industrial practice of a plant in China demonstrated that roasting with electromagnetic furnace is a feasible method to remove flotation agent used in the process of tungsten concentrate flotation. This method has advantages of excellent removal of floating chemicals, low energy consumption, high degree of automation and environmental friendlyness. Electromagnetic furnace is thus recommended in this project.

4.2.2 Soda high pressure leaching

Soda high pressure leaching is carried out in alkaline medium with 22 atm operation pressure. Steel high pressure reactor of 10 m^3 with far infrared electric heating and design pressure of 36 atm is recommended. The equipment has been widely used and can be purchased in China.

4.2.3 Filtration of leach solution

In general, the leach solution of tungsten concentrate exhibits good filtration performance. Full automatic vacuum belt filter is recommended for L/S separation since it has advantages of good filtration performance, high washing efficiency and automation degree, low labor intensity and easy operation.

4.2.4 SX

Mixer settler, extraction tower and centrifugal extractor are three main equipments in SX. In this project, annular centrifugal extractor is recommended since it has advantages of fast and good phase separation, small organic retention volumn and high automation degree. Pilot plant and industrial test of SX in alkaline medium demonstrated the reliability of the equipment.

4.2.5 Complete removal of Mo

Since the separation of ammonium tetrathiomolybdate and ammonium tungstate is a chromatographic process, the moving bed and fluidized bed IX

columns are recommended for Mo adsorption and Mo stripping from loaded resins, respectively. The equipment has been successfully and widely applied in the field of hydrometallurgy and pharmacy. It has advantages of low investment, small resin demand, continuous operation and fast stripping speed.

4.2.6 APT crystallization

According to the project scale and mature experience, 10 m^3 enamel reactor or Ti lined reactor with jacket heating is recommended for APT crystallization in intermittent operation. Vacuum belt filter system in automatic operation is recommended for the L/S separation.

4.2.7 APT Drying

Far infrared dryer, double cone rotary vacuum dryer and microwave heating dryer are three main mature equipments for APT drying in industry. Among them, microwave heating dryer has been successfully and widely used in metallurgical industry of tungsten and molybdenum in recent years since its energy saving, easy control and continuous operation. Therefore, microwave heating dryer is recommended in this project.

4.2.8 Recovery of tungsten from crystallization mother liquor

Tungsten in crystallization mother liquor of APT and mother liquor after MoS_3 precipitation can be recovered using IX. Fixed bed column is recommended. The effluent containing $(NH_4)_2SO_4$ after W adsorption by resins can be concentrated and crystallized using four effect evaporator. Continuous centrifuge can be then used for L/S separation to produce industrial $(NH_4)_2SO_4$. Four effect evaporator is an energy saving equipment, which needs only 0.4 tonne saturated steam for 1 tonne H_2O evaporation each.

4.3 List of equipment

List of main production equipment is shown in Table 4-1.(Special environmental protection equipment excluded)

Table 4-1 List of main production equipment

Step	No	Equipment	Model specifications	Texture of material	Amount	Total power (KW)	Price (Ten thousand RMB)
Roasting	1	Belt conveyer	>20 m	Steel	1	5.0	20

Chapter 5 Workshop and layout

5.1 Workshop

There are three workshops of roasting and leaching, APT product and water treatment.

5.2 Plant allocation principle and characteristics

（1）Follow the process flowsheet and material flow, easy operation and convenient equipment repair.

（2）Zoning according to qualitiy requirement and scientific management of intermediate and final product.

（3）Reasonable layout of material flow and stream of people for safe production.

5.3 Equipment layout

Ore bunker and electromagnetic furnace: 66×15 m^2 Monolayer roasting workshop

High pressure leaching and filtration: 66×15 m^2 Double-story leaching workshop

SX: 80×10 m^2 4 storys workshop

W-Mo separation, crystallization and drying: 80×10 m^2 4 storys workshop

Water treatment（DI water and waster water）: 30×15 m^2 Double-story workshop

Analysis room and machine repair shop: 6×24 m^2 4 storys workshop

Boiler room: 15×30 m^2 Monolayer workshop

Liquid material（NaOH, H_2SO_4 etc.）: 15×80 m^2 Monolayer workshop

Auxiliary material, canteen and office: 60×15 m^2 4 story of building.

Chapter 6 Public facilities, civil engineering and transportation

6.1 Transport volume
External total transport volume: 30,499 tonnes,
in which: 13,842 tonnes of plant-in quantity,
16,657 tonnes of plant-out quantity
All can be transported by truck. Detailed transport volume is shown in Table 6-1.

Table 6-1 Material transport volume （Unit: tonne/year）

Material	Plant-in	Material	Plant-out
Scheelite concentrate	6,362.0	APT	4,500.0
NH_4HCO_3	1,125.0	Residue containing high content of Mo	25.0
Caustic soda	495.0	$(NH_4)_2SO_4$	750.0
Ammonia	270.0	Leach residue	3574.0（H_2O%: 15%）
$(NH_4)_2S$（S%: 8%）	450.0	Na_2CO_3	7358.0（H_2O%: 65%）
H_2SO_4	390.0		
Coal	2,250.0	Coal ash	450.0
Others	2500.0		
Total	13,842.0		16,657.0

6.2 Water supply and drainage
6.2.1 The balance of water supply and drainage
The balance of water supply and drainage is shown in Table 6-2 and and Figure 6-1.

6.2.2 Water supply
（1）Water supply for production line
Total amount: 1415.4 m^3/d
In which: Fresh water consumption: 141 m^3/d
circulating water amount: 1273.4 m^3/d, 90% of total amount.
Water evoparation amount: 136.6 m^3/d
Water content in APT product: 5.4 m^3/d
Waste water emission: 0.0 m^3/d.
（2）Domestic water supply
Total amount（including bathroom, WC and canteen...）: 20 m^3/d fresh water.
（3）Total water supply: 161 m^3/d
Fresh water supply for production line: 141 m^3/d
Fresh domestic water: 20 m^3/d.

Table 6-2 The balance of water supply and drainage (m^3/d)

No	Step	Total amount	Fresh water	circulating water	Water consumption
1	Roasting	200.0	10.0	190.0	10.0
2	Leaching-filtration	345		326	19
3	SX	306.4	64	306.4	0
4	Ion exchange for Mo removal	115	18	115	0
5	APT crystallization	93	3	81	12
6	W recovery form mother liquid	76		76	0
7	Boiler room	185	45	140	45
8	Plant washing	10.0	1.0	9.0	1.0
9	Waste water treatment	69.6		30	39.6
10	Cooling water	15.4	0	0	15.4
Total		1415.4	141	1273.4	142

6.2.3 Water drainage
"Zero emission" of polluted water in production line
Domestic sewage can be collected and treated using MBR sewage processor, the resultant water can be recycled for planting.

6.3 Electric power and communication
6.3.1 Power supply
Power supply includes plant distribution, plant lighting and ground connection. Electricity load is calculated based on electrical equipment as follows:
Equipment installed capacity: 3,994.5 KW.
Plant lighting: 120 KW
Load grade is Grade 2 and Grade 3.

6.3.2 Thermal
6.3.2.1 Boiler room
Spare boiler is available to meet the steam requirement of 24 h operation. Coal is employed as fuel and mechanical coal feeding system is also employed.

The pressure of steam is under 0.6 Mpa. Two steam boilers are equipped. Two-boiler operation for heating season, and 1 boiler operation, 1 boiler spare for non-heating reason.

6.3.2.2 Compressed air
It is required at pressure of 0.6~0.7 Mpa without oil, water and dust. Air compression station with screw type air compressor is recommended to ensure the supply of compressed air.

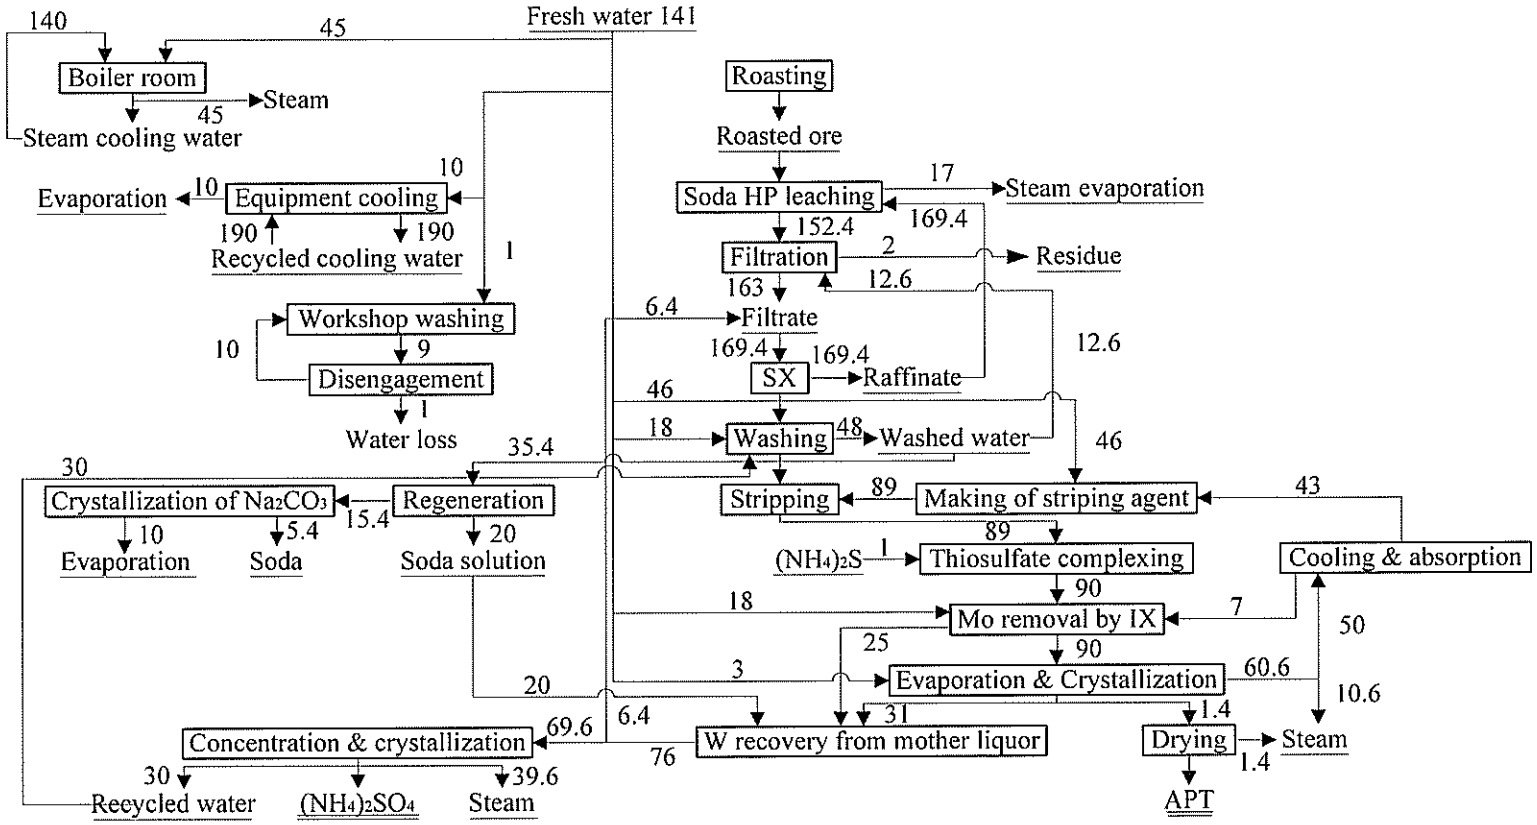

Figure 6-1 The daily balance of water supply and drainage on APT production line（unit: m^3）

6.4 Civil engineering

The main production plants include roasting, high pressure leaching and APT product workshop. The auxiliary buildings include boiler room, sewage treatment station, water treatment station, raw materials and product warehouse（already included in roasting and APT product workshop）, liquid material storage tank zone and comprehensive building. The main buildings list is shown in Table 6-3.

Table 6-3 Main buildings list

No.	Building	Built-up area （m^2）	Price（10,000 RMB）	Remarks
1	Roasting	15×66=990	89	Light steel
2	Leaching, filtration	15×60（2 storys）=1980	396	Frame structure
3	SX	12×80 （4 storys）= 3840	768	Frame structure
4	W-Mo separation, APT production	12×80 （4 storys）= 3840	768	Frame structure
5	Analysis room and machine repair shop	6×24（4 storys）=576	69.2	Brick masonry structure
6	liquid material storage tank zone	15×80=1200	48	Light steel
7	Spare parts warehouse and comprehensive building	15×60（4 storys）=3600	720	Frame structure
8	High voltage distribution room	15×24= 360	43.2	Brick masonry structure
9	Boiler room	15×30= 450	90	Frame structure
10	Chimney	25 m×Φ8 m	28	Brick structure

16	Intermediate tank	10×7×5 m×2 tanks	60	Steel reinforced concrete + anticorrosive
17	Accident pool	10×7×5 m	40	Steel reinforced concrete + anticorrosive
Total			3,333.4	

Chapter 7 Waste treatment and environmental protection

7.1 Environmental protection standards
7.1.1 Rules and regulations adopted by
《Environmental Protection Law of the People's Republic of China》（1989.12.26）
《The People's Republic of China Air Pollution Control Act》（1995.8）
《The People's Republic of China Solid Waste Pollution Prevention Law》（1996）
《Construction Project Environmental Protection Management Regulations》（State Council No. 253）
《The decision of the State Council on a number of issues of environmental protection》（National Development 《1996》 No. 31）

7.1.2 Standards adopted by
《Ambient Air Quality Standard》（GB3095-1996）
《Surface water environmental quality standards》（GB3838-2002）
《Integrated Wastewater Discharge Standard》（GB8978-1996）
《Air Pollutant Comprehensive Discharge Standard》（GB16297-1996）
《Emission standards for odor pollutants》（9078 1996）
《The boiler air pollutants emission standard》（GB13271-2001）
《Industrial furnace air pollutants emissions standards》（GB9078-1996）
《Boundary of Industrial Enterprises noise standard》（GB12348-1990）

7.2 Major sources of pollution, and pollution emission status and control
7.2.1 The main source of pollution and the types of pollutants and the quantity
As a result of advanced cleaning process of this project, wastewater, waste residue and waste gas can meet the emission standards after treatment, in which wastewater for the near zero emission. The amount, nature and main components of the waste gas, wastewater, waste residue and the noise generated from this project are shown in Table 7-1.

7.2.2 Pollution control and pollutant emission
7.2.2.1 Waste gas
Waste gas in this project is generated from the process of electromagnetic furnace roasing, APT crystallization, $(NH_4)_2SO_4$ concentration and boiler waste gas.

The generation of roasting waste gas is about 60,000 m^3/d. Main components of the waste gas are air, CO_2 and small amount of dust with 5.0 g/m^3 which is the pollutant. The waste gas is in turn passed through settling chamber for dust collection and cooling, bag-type collector for dust removal and chimney for emission. The solid dust collected in settling chamber and bag-type collector can be merged with calcine into the step of soda high pressure leaching. The bag-type collector is recommended by Chinese Ministry of environmental protection, the dust removal reaches 99%. After treatment, the dust concentration is less than 50 mg/m^3, which meets the 1A emission standards

of GB9078-1996 and GB16297-1996.

Table 7-1 Main pollutants list

Pollutants		Generating source	Components	Amount
Waste gas	Roasting waste gas	Roasting	Air, CO_2, small amount of dust (~5.0g/ m^3)。	~60,000 m^3/d
	Waste gas from APT crystallization and $(NH_4)_2SO_4$ concentration	APT crystallization	Steam, air, CO_2, NH_3 (~10 g/m^3)	~45,000 m^3/d
	Boiler flue gas	Boiler room	Dust, CO_2, SO_2	~300,000 m^3/d
Production sewage	Effluent of ion exchange of W	Metal recovery from mother liquid after crystalliztion	pH=3~4, $(NH_4)_2SO_4$	~50 m^3/d
Production wastewater	Workshop washing waste water	Workshops	Suspended solids	9.0 m^3/d
	Life waste water		COD, SS	10 m^3/d
Waste residue	Coal ash	Boiler room	SiO_2	~1.4 tonne/d
	Leach residue	Soda leaching	$CaSiO_3$, $CaCO_3$	11.0 tonne/d
Noise	Noise	Air compressor, fan, vacuum pump, roasting furnace		

The generation of waste gas from process of APT crystallization and $(NH_4)_2SO_4$ concentration is about 45,000 m^3/d. Main components of the waste gas are water steam, air and NH_3 which is main pollutant. The waste gas is in turn passed through heat exchanger for cooling followed by washing tower for absorption with H_2SO_4. The removal of NH_3 is more than 99%. After drip washing, the waste gas can be discharged through a 15 m long chimney, which meets the 2A emission standard of GB14554-1993. Ammonia solution obtained by cooling can be used to make stripping agent of tungsten. Ammonium sulphate obtained by drip washing can be merged with

$(NH_4)_2SO_4$ waste water for further treatment.

Boiler fuel gas contains SO_2, smoke and dust. The matching desulfurization dust equipment provided by boiler manufacturer can be used to treat boiler fuel gas. After treatment, the waste gas meets emission standard of GB13271-2001 and can be discharged.

7.2.2.2 Waste water
Waste water in this project includes production sewage, production wastewater and domestic sewage.

The generation of domestic sewage is about 15 m^3/d, the sewage can be treated using MBR sewage processor and then recycled for planting.
The production wastewater is generated from equipment and ground washing, it normally contains small amount of suspended particulate matter. After sedimentation, the supernatant can be recycled for the washing. The sediment is sent to slag yard for stacking.

The production sewage is mainly generated from the process of IX of tungsten. The mother liquor after APT crystallization mainly contains ammonium paratungstate (~20 g/L WO_3) and ammonium sulphate with pH of 6~7. After pH adjustment to 3~4 using mother liquor after Mo precipitation and H_2SO_4, the solution can be used to recover tungsten by IX. The effluent of IX is the waste water, which is acidic solution containing $(NH_4)_2SO_4$ with pH of 3~4 and generation of 36.6 m^3/d. The waste water is merged with elution of tail gas using H_2SO_4 after APT crystallization. The mixed solution can be used to produce $(NH_4)_2SO_4$ crystal by multiple effect evaporator. The $(NH_4)_2SO_4$ crystal can be sold as by-product.
The cooled water from roasting and leaching can be recycled.
From the discourse above, there is no waste water emission in the process of APT production.

7.2.2.3 Waste residue
The residue from leaching mainly consists of calcium silicate and calcium carbonate and small amount of calcium phosphate salt, which is stable and non-toxic. Recommended to build up a field for storage and sold to the construction enterprise or landfilled when it accumulates to a certain amount.

Daily coal ash which produced from the boiler room is about 1.4 tonnes, it can be used as construction materials. It is better to build up a slag yard for temporary storage of the coal ash, and then sell to the construction enterprise when it accumulates to a certain amount.

MoS_3 which produced from the process of W-Mo separation is an advanced raw material for Mo metallurgy, and it can be also sold without processing.

7.2.2.4 Dusting removal
Besides the dust from roasting, there is also a small amount of APT particles of dust from the proces of APT drying, sieving and packaging. The dust is blowed

to a bag de-dusting system, the removal of dust can reach 99.5%, which meets the emission standard.

7.2.2.5 Noise

The noise of this project comes from the electromagnetic roasting furnace, filter, stirring equipment, fans, air compressors. Based on the principles of noise generation and dissemination, the noise control can be carried out on the sound insulation and sound-absorbing, local elimination of the strong sound source. Workers who work in the strong sound source area have to be equipped with protective equipment. It also needs to strengthen the greening in factory district. After taking measures above for the noise control, It will be able to meet II class of 《Industrial Enterprise Noise Standards》（GB12348-90）.

7.3 Investment on environmental protection

Environmental protection facilities of the project mainly clude the roasting exhaust collection system, condenser and scrubbing tower for the exhaust from APT crystallization, the device for the pre-concentration, concentration and crystallization of ammonium sulfate waste water, desulphurization and de-dusting system of boiler room, chimney, waste water sedimentation tank, domestic waste water treatment tank and anti-noise green belt.

Project investment on environment protection is about 7.2 million RMB, accounting for 5.12% of the total investment on fixed assets.

Chapter 8 Organization and labor arrangement

8.1 Work system
Employee work 40 hours a week according to the Labor Law of the People Republic of China, shift work for continuous production line workers is four shifts with three changing, day shift workers work five days a week.

Continuous working system is adopted, 320 working days a year, three shifts a day, 8 hours each shift.

8.2 Labor arrangement
According to the position requirement, the total staff members are estimated 93 which include 78 productive workers, 15 administrators and technical staff. The enrollment of new productive line workers will be employed from the whole society and based on the competitive selection. The technical staff are mainly from the internal training and can also be employed from tungsten metallurgy field who is professional on engineering technology. Administrators are from the head office. Project labor arrangement is shown in Table 8-1.

8.3 Productivity
After the completion of the project, yearly monetary labor productivity is as follows:

The overall labor productivity: 9.4 million RMB/year/capita

Production workers productivity: 11.256 million RMB/year/capita

8.4 Wages and benefits
The determination of wage levels is in accordance with the characteristics of the enterprise and job tasks.

Production workers and service staff have an average 60,000 RMB/year/capita

Managers and technician: 120,000 RMB/year/capita

Estimated total project yearly salaries: 6.48 million RMB/year

Estimation of pensions, medical benefits, work compensation and welfares: 908,000 RMB/year, which is 14% of the total salaries. Total wage cost is 7.388 million RMB/year.

Wage costs for APT product is 1,642 RMB/tonne.

Table 8-1 Labor arrangement

No	Project title	Personnel on the payroll		
		Sub total	In which	
			Production staff	Manager and technician
1	Main production work			
1.1	Roasting, leaching and filtration	14	12	2

	Total	93	78	15

Chapter 9 Construction investment estimation

9.1 Project summary

The project includes APT production line of 4,500T/year and accessory engineering.

Fixed investment expenses is 140,672,000 RMB, including construction expenses of 33,334,000 RMB, equipment expenses of 33,355,000 RMB, installation costs of 12,167,000 RMB, environment protection investment of 7,200,000 RMB, other expenses of 43,028,000 RMB, and unforeseen expenses of 11,588,000 RMB of project.

9.2 Investment estimation basis

（1）Work quantities and the related information date

（2）Equipment price is estimated according to the Chinese factory enquiry in 2012, and the cost of transportation is charged on 5% of the original equipment price.

（3）Project cost refers to the similar project estimation cost in the south of the Yangtze River in China.

（4）Installation costs are estimated according to the China Non-ferrous metal industry engineering construction quota index and this project practical situation. Also refer to the similar completed project estimation.

（5）Other construction costs refer to the Non-ferrous metal industry project construction quota index which was regulated by the China Non-ferrous metal industry association in 2008.

（6）According to 《Regulations of Project Survey and Design Expenses》 which is issued by the Chinese Committee of Planning and Ministry of Construction.（《2002》10）

（7）Construction of China's State Development Planning Commission interim provisions on investor advisory fees（《1999》1283）

（8）Unforeseen expenses: including cost of the project, as well as fixed assets, intangible assets, and other costs and other fees, the tariff takes 10%.

（9）The expenses of land use, site levelling and basis exploration are not included in the investment estimation.

9.3 Construction investment estimation results

The construction investment estimation is shown in Table 9-1.

9.4 Estimation of floating capital

The floating capital occupied by the enterprise to maintain normal production and the amount of total working capital including reserve funds, current fund for production, end product fund and other current distribution realm revolving fund, carries on the collection of those funds according to enterprise's production load. The project is commissioned by the monthly production volume of 420 tonnes. Capital return period is 60 days. Based on the purchase of scheelite concentrate at market price, the estimation of floating capital is about 150,000,000 RMB in this project.

9.5 Total investment in the project

The total investment of project construction is 290,672,000 RMB, including static investment expenses of 140,672,000 RMB and floating capital of 150,000,000 RMB

Table 9-1 Project construction investment estimation （unit; ten thousand）

No.	Expense titles	Price	Remarks
1	Construction project	3333.4	
2	Purchase of equipment	3335.5	
3	Installation and piping	1216.7	
4	Environmental protection equipment and facilities	720	
5	Start-up costs	760	Exploration, Engineering supervision, environment and safe evaluation, insurance, etc

Chapter 10 Productive consumption and cost

10.1 Production cost estimation

Production costs include direct material costs, direct fuel and power costs, direct labor and welfare, manufacturing costs and other direct expenditures.

The direct material produces in the operation process including the enterprise actual consumption material, accessory material, purchased half-finished product, fuel, power, packing and other direct materials. The raw material, power consumption index is calculated according to data provided by the industrial professionals.

scheelite concentrate containing WO_3>65% is provided by Skarn Mine of Venture Minerals Limited in Australia. Raw and auxiliary materials and fuel are supplied by local market. The purchasing price refers to the recent Chinese market average price, fuel and power prices are on the basis of project newly built area determination. The main raw and auxiliary material, fuel and power price including taxes is as indicated in Table 10-1. Raw materials, fuel, and power consumption cost is estimated as shown in Table 10-2.

Table 10-1 Price for main materials, fuel and power

No.	Title	Unit (RMB)	Prices (include tax)	comments
1	Scheelite concentrate	Yuan/t	121,000	WO_3 : 65%
2	NaOH	Yuan/t	3,000	
3	$NH_3 \cdot H_2O$	Yuan/t	3,200

3	Coal	T	900	0.50	450.00	

10.2 Direct labor expenses and walfares

The direct wages of project is 6,480,000 RMB/year, welfare and benefits costs are estimated on 14% of the wages, which is 908,000 RMB/year, the total is 7,388,000 RMB/year. Wage cost for APT product is 1,642 RMB/per tonne.

10.3 Other expenses

Other expenses include depreciation costs, management costs, financial costs and sales costs.

The depreciation year of fixed assets is calculated based on the method of

average age classify as follows:
Houses and buildings: 30 years
Machines and equipment: 15 years
Fixed assets net value: 5%.
The depreciation costs in production year: 6,284,000 RMB. For APT product is 1,396.4 RMB/per tonne.

Management costs:
In production year: 1,575,000 RMB. For APT product is 350 RMB/per tonne.

Financial costs:
Construction investment loan is not taken as consideration in this project. Only 50% of floating capita loan interest occurred in loan year is calculated.
In production year: 682,500 RMB. For APT product is 170 RMB/per tonne.

Sales cost:
Sales costs are calculated by 0.3% of the sales income.
For APT product is 582 RMB/per tonne.

10.4 Total costs
Total costs consist of manufacturing costs, management expenses, financial costs and sales costs.
Total costs in production year: 799,040,700 RMB.
For APT product is 177,564.6 RMB/per tonne.

10.5 Sales income
Because of the frequent fluctuation in the market of tungsten product, the sales price is calculated according to the current domestic market price(April, 2012).

APT: 194,000 RMB/tonne
$(NH_4)_2SO_4$ (N%:21%) : 600 RMB/tonne
High content of Mo residue (Dry basis) : 38,200 RMB/tonne
Na_2CO_3 (including H_2O) : 480 RMB/tonne
Yearly sales income of the project is shown in Table 10-3.

Table 10-3 Project yearly production sales income

Products	Prices with tax (ten thousand yuan/tonne)	Sales volume (ton)	Sales income (ten thousand yuan)
APT	19.4	4,500	87,300
$(NH_4)_2SO_4$	0.06	750	45
High content of Mo residue	3.82	25	95.5
Na_2CO_3 (including H_2O)	0.048	7,358	353.2
Total			87,793.7

Chapter 11 Conclusions and Suggestions

11.1 Conclusions

（1）The raw material for this project is scheelite concentrate. Sangdong Mining Corporation of South Korea owns the tungsten ore with stable and reliable resources, which laid material foundation for the project.

（2）The proposed process flowsheet of APT production line is advanced and reliable. International advanced technology of SX of tungsten in alkaline medium and moving bed IX for molybdenum removal is applied, which has been successfully employed for industrial production, demonstrating reliability and feasibility of the technology.

（3）There is almost zero emission of wastewater because of the reusing, and only small amount of waste residue and waste gas is discharged after treatment. The project conforms to the environmental protection requirements.

（4）The project equipment is advanced and experienced test of practice, equipment production time is short, and no special design requirement.

（5）The completion of project can provide employment opportunities for more than 90 people, it is useful to alleviate social employment pressure, which has some social benefit

（6）The total investment for project is 290,672,000 RBM, including fixed assets of 140,672,000 RMB and floating capital of 150,000,000 RMB.

（7）After the project completes, the annual sales income may achieve 877,937,000 RMB, creating the profit of 71,296,300 Yuan. The project exsits fine economic index and economical feasibility.

（8）Comprehensive analysis shows that the project exsits advanced process, friendly environment, stable raw material supply and good economic benefits, which should be a very good opportunity of investment.

11.2 Suggestion

Before the project commences, it is suggested that scheelite concentrate is applied to carry out the confirmatory test of whole process recommended in this report, ensuring the practicality of process recommended and the reliability of achievement of targets. The results of confirmatory test can provide the basis for project design.

1 Preface

Guangzhou Research Institute of Non-ferrous Metals (GZRINM, for short later) was commissioned by Venture Minerals Ltd, Australia to carry out a laboratory test on the two kinds of ores (Main Skarn Ore—VMMS for short and 2# Skarn Ore—VM2S for short) containing sulfide-magnetite-scheelite-cassiterite minerals from Lindsay Deposit, Tasmania, Australia with the object of providing a basis for plant feasibility study and preliminary design. As the sulfide and magnetite in samples were already recovered in Australia using sulfide flotation and LIMS after sample's being ground to P80-120 micron, the contract requires to carry out lab test and to gains the scheelite concentrate which meets the quality requirements with reasonable higher recovery and to remain the cassiterite in tailings as much as possible.

The trial adoption of WHGMS is conducted to reject lots of paramagnetic gangue minerals aiming to upgrade the head ore, but it is not satisfactory, as a quite amount of scheelite and cassiterite minerals are lost in the Mags fraction. So basically, the flow-sheet of flotation-gravity separation-flotation is adopted

The entire test has been basically completed by the end of June, 2012, lasting about 3 and half months. In the middle of period of test time, the technological flow-sheet and quantitative flow-sheet of lab locked cycle

test for Main Skarn sample and 2# Skarn sample were provided to Venture Minerals Ltd. in accordance with the contract requirements. The final results are shown in Table 1-1, Table 1-2 and Table 1-3.

Table 1-1 Test results of VMMS

The above results have fully completed the task of lab test.

2 Preparation and processing of test materials

The two samples were already treated in Australia to remove the sulfide and magnetite using sulfide flotation and LIMS after sample's being ground to P80-120 micron, the samples are with a little moisture. The samples are split manually for tests.

The processing flow-sheet of test materials is shown in Figure 2-1.

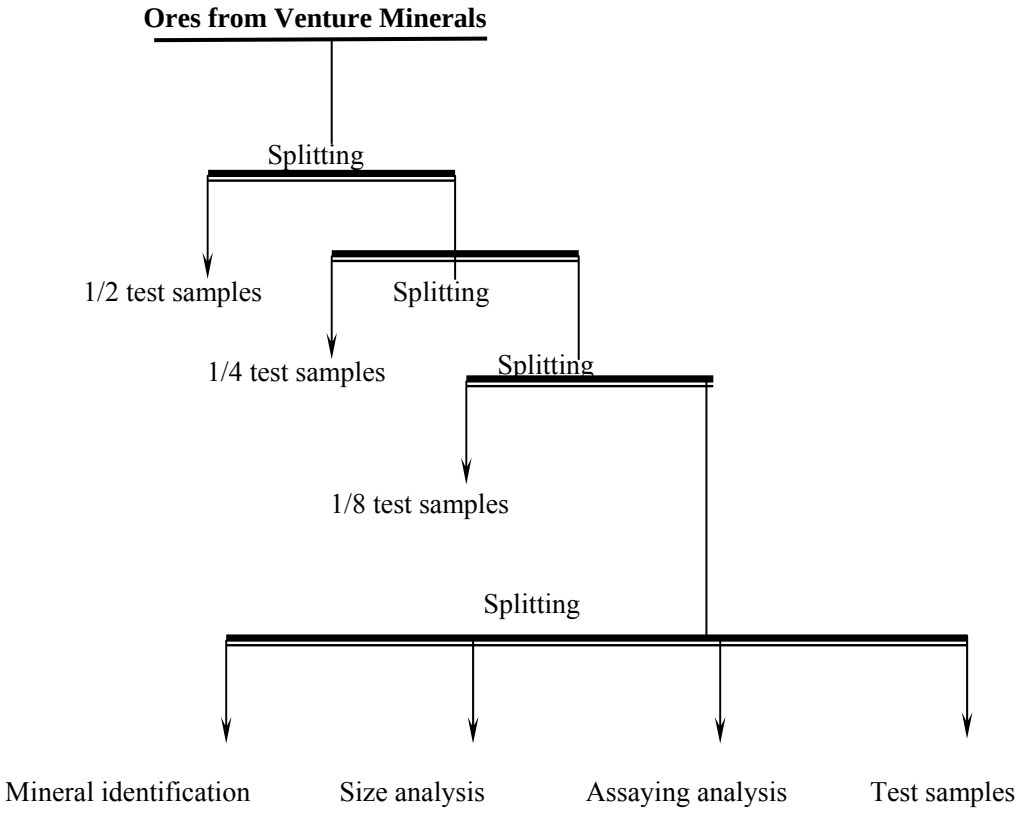

Figure 2-1 the processing flow-sheet of test materials

3 Physical and chemical properties of ores

3.1 Physical and chemical properties of Main Skarn Ore(VMMS)

The results of chemical multi-elemental analysis, phase analysis and size distribution of head of main Zone ore are shown respectively in Table 3-1, Table 3-2, Table 3-3 and Table 3-4, respectively.

Table 3-1 Results of multi-element chemical analysis for VMMS

4. Study on process mineralogy of ore

4.1 Study on process mineralogy of VMMS sample

4.1.1Composition of sample

The results of multi-element chemical analysis of the sample are shown in Table4-1.

Table4-1 Results of multi-element chemical analysis

Element	WO_3	Sn	Fe	Mo	CaO	SiO_2	K_2O
Abundance %	0.22	0.50	19.80	<0.01	11.13	32.60	3.48

Abundance %	2.91	0.30	0.11	0.35	0.03	7.67	0.49

4.1.2 Mineral composition of sample

The mineral composition of sample was determined and quantitatively measured by optical microscope and MLA. According to the results shown in Table4-2, tungstate minerals are dominated by scheelite with a very small amount of wolframite and the ratio of scheelite to wolframite is 27 to 1; tin minerals mainly are cassiterite, a trace of stannite and stokesite; sulfide minerals are of great varieties but only a small amount with a total of about 1% and include pyrrhotite, pyrite, a trace of chalcopyrite, chalcocite, arsenopyrite, etc.; iron oxide minerals are magnetite and siderite which can be recovered comprehensively, while other oxide minerals include vonsenite, a small amount of ilmentite, limonite, rutile, etc.; gangue minerals are dominated by biotite and

amphibole, followed by vesuvianite, pyroxene, andradite, calcite, quartz, feldspar, chlorite, etc..

Table 4-2 Results of quantitative measurement

Mineral	Abundance %	Mineral	Abundance，%
Scheelite	0.243	Helvite	0.146

Rutile	0.119	Fluorite	0.467
Zircon	0.01	Diaspore	0.034
Apatite	0.282	Others	0.124
Monazite	0.002	Total	100.000
Parisite	0.001		

4.1.3 X-ray diffraction analysis

According to the X-ray diffraction spectrum of sample shown in Figure 1, the minerals of a large quantity are biotite, amphibole, vesuvianite, siderite, etc..

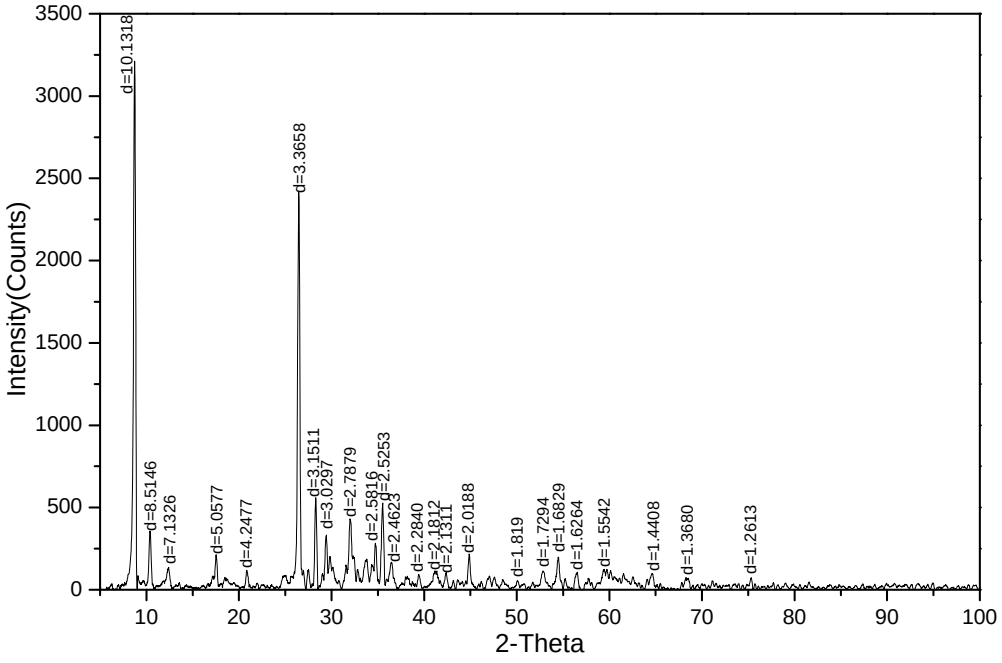

Figure 1 X-ray diffraction spectrum of sample

4.1.4 Mineral grain size distribution

The grain size distribution shown in Table 4-3 indicates that the grain size of scheelite is uneven and the size range is extensive; each size fraction is almost equal in amount. The scheelite grains less than 0.01mm account for more than 25% in which the grains less than 0.005mm occupy 15%. Obviously, the scheelite is overground. The grain size of cassiterite is even with the main size range of 0.01~0.16mm, the amount of micro-fine size fraction of which is far less than that of scheelite.

Table 4-3 the grain size distribution of scheelite and cassiterite

Size mm	Mineral grain size distribution %	
	Scheelite	Cassiterite
-0.16+0.08	10.64	13.10
-0.08+0.04	16.86	23.34
-0.04+0.02	27.73	32.92
-0.02+0.01	18.79	15.63
-0.01+0.005	10.96	9.27
-0.005	15.02	5.74
Total	100.00	100.00

4.1.5 Mineral liberation

The liberation degree of scheelite and cassiterite in each size fraction was measured and the results are shown in Table 4-4. Based on the results, the dissociation of scheelite is good while the liberation degree of cassiterite is low especially in the coarse size fraction. The liberation degree of scheelite is up to 89.08% while that of cassiterite is only 53.72% at the grinding fineness of 72.56%-0.075mm.

Table 4-4 the liberation degree of scheelite and cassiterite

Size mm	Yield %	Assay %		Liberation degree %	
		WO_3	Sn	Scheelite	Casseriterite

-0.075+0.043	24.54	0.61	0.26	84.39	59.87
-0.043	48.02	0.66	0.17	99.37	79.05
Total	100.00	**0.56**	**0.26**	**89.08**	**62.15**

4.1.6 Physical and chemical properties and the dissemination state of minerals

4.1.6.1 Scheelite $Ca(WO_4)$

Scheelite is the main mineral to be recovered and the abundance is

0.243%. Its crystals appear as tetragonal dipyramid or equiaxed granular, colorless and transparent. The scheelite of tungsten concentrate appears as crushed granular, oily luster, medium hardness (4.5), density 5.8-6.2g/cm^3, brittle and a clear cleavage. According to the Energy-dispersive X-ray spectroscopy ("EDS" for short) analysis results of chemical composition shown in Table 4-5, the scheelite in this sample contains a small number of irons. The chemical analysis results of pure scheelite are: WO_3 79.59%, Mo 0.20%.

Table 4-5 the EDS analysis results of chemical composition of scheelite

Measuring point	Chemical composition %		
	WO_3	CaO	FeO
1	78.80	21.15	0.05
2	79.54	20.01	0.45

9	78.71	20.19	1.09
10	79.29	20.41	0.30
Average value	79.37	20.34	0.30

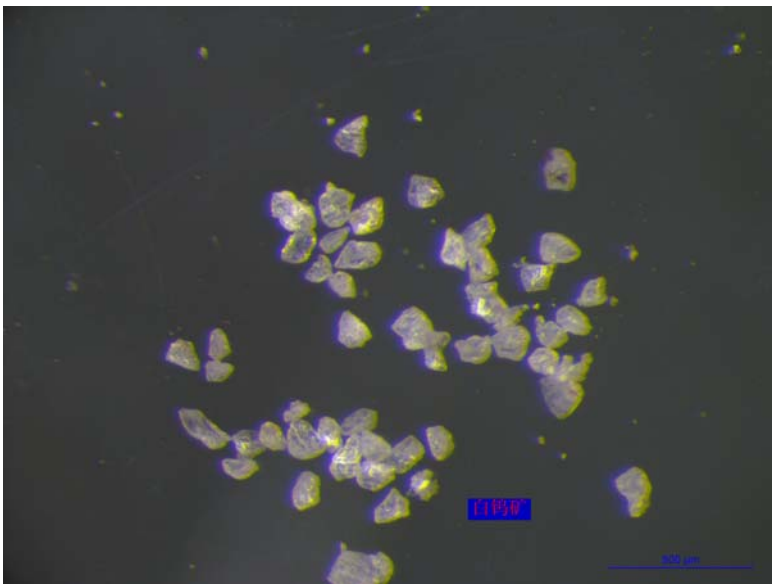

Photo 1 Stereomicroscope to magnify 50 times
Scheelite particles

The scheelite of sample exists in the following forms: □ most of scheelite is monomer (see photo 2); ② scheelite is intergrown with the gangue minerals such as amphibole, garnet, serpentine, calcite, etc.(see photos 3, 4, 5); ③ scheelite is intergrown with the metallic minerals such as pyrrhotite, cassiterite, etc. (see photos 6, 7); ④ a small amount of micro-fine scheelite is included in amphibole, which is hard to be dissociated (see photo 8).

4.1.6.2 Wolframite $(MnFe)WO_4$

The abundance of wolframite is 0.009%. Wolframite crystals usually appear as thick tabular or short prismatic. The color changes with the content of iron and manganese. The higher content of iron it contains, the darker color it is. It has the hardness of 4-5.5 and density of 7.18-7.51g/cm^3 which also increases with the iron content increasing. The wolframite which is rich in iron has weak magnetism. The wolframite of sample is rare. It is occasionally seen that granular wolframite is intergrown with magnetite and biotite (see photo 9). Besides, rare wolframite is metasomatized by scheelite (see photo 10).

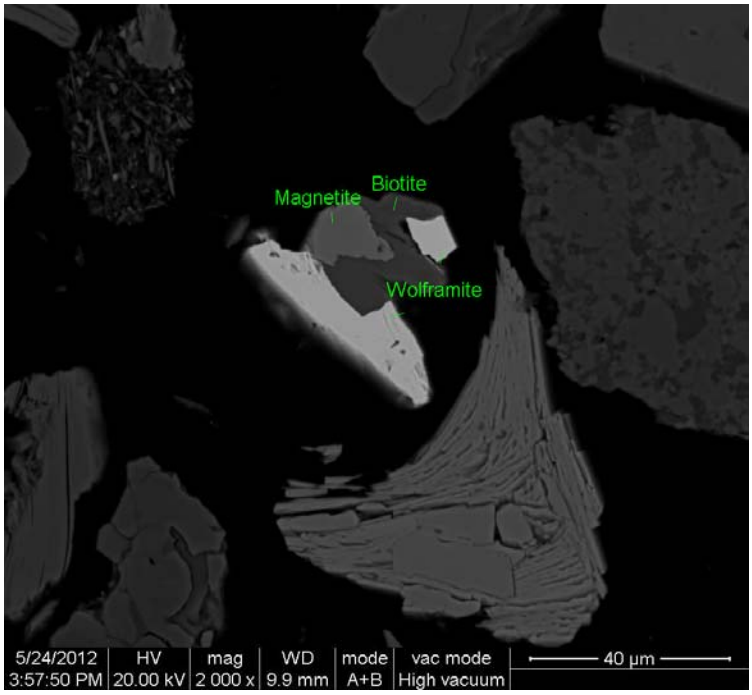

Photo 9 SEM to magnify 2000 times
Wolframite is intergrown with magnetite and biotite.

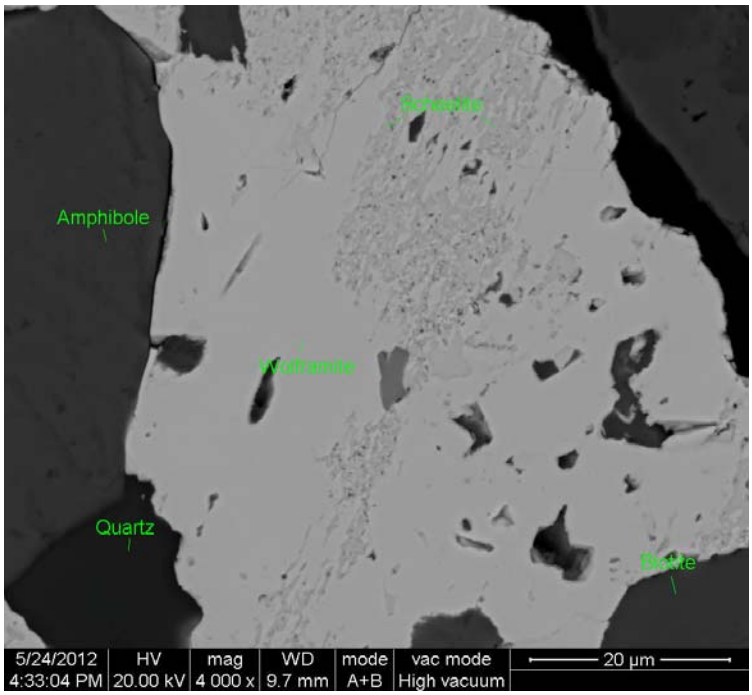

Photo 10 SEM to magnify 4000 times
Wolframite is metasomatized by scheelite.

4.1.6.3 Cassiterite SnO_2

The abundance of cassiterite is 0.563%. Its theoretical chemical composition is: Sn 78.80%, O 21.20%, but usually with mixed iron and other elements. According to the EDS analysis results of chemical composition shown in Table 4-6, the cassiterite of this sample generally contains a few impurities of Fe and Si. Cassiterite appears as brown to black colors, adamantine luster. It is brittle and has the Mohs hardness of 6-7 as well as density of 6.8-7.0g/cm^3.

Most of cassiterite appears as monomer (see photo 11), but still a lot of cassiterite is closely intergrown with biotite, siderite and magnetite, in which the intergrowth between cassiterite and biotite is the most closely. There is not only cassiterite including maicro-fine biotite inclusions, but also cassiterite being included in biotite (see photos 12, 13, 14, 15, 16).

Table4-6 the EDS analysis results of chemical composition of cassiterite

4.1.6.4 Stannite Cu_2FeSnS_4

The theoretical chemical composition of stannite is: Cu 29.58%, Fe 12.99%, Sn 27.61%, S 29.82%. Because stannite often includes the micro-fine sphalerite, chalcopyrite and other inclusions, it usually contains zinc, silver and other elements. Stannite appears as steel-gray to iron-black colors or yellow-gray color when it contains a lot of chalcopyrite inclusions. It is opaque, brittle and has metallic luster, the Mohs hardness of 3-4 and density of 4.30-4.52 g/cm^3. Based on the EDS analysis results of chemical composition shown in Table 4-7，this stannite generally contains zinc, aluminum, silicon, etc.. The abundance of stannite is rare, only 0.002%.

Table 4-7 the EDS analysis results of chemical composition of stannite

Measuring Point	Chemical composition %						
	Sn	Zn	Cu	Fe	S	Al	Si
1	27.60	0.77	29.67	14.18	27.49	0.11	0.18

The crystal stock of stannite and sphalerite is included in

4.1.6.5 Ludwigite-vonsenite $(Mg, Fe)_2 Fe^{3+}[BO_3]O_2$

It is completely isomorphous between Mg and Fe^{2+} in the composition of ludwigite-vonsenite. It can be divided into ludwigite and vonsenite in

accordance with $Mg>Fe^{2+}$ or $Mg<Fe^{2+}$. The XRD spectrum of vonsenite in this sample is shown in Figure 2 and the EDS analysis results of chemical composition are shown in Table4-8. Based on the results, the vonsenite is rich in Fe and poor in Mg, and generally contains the isomorphous Sn with the Sn content changing greatly. Ludwigite-vonsenite appears as dark green to balck colors (the color becomes dark with the iron content increasing), light greenish black to black streak, dim luster but silky luster on the fresh surface of fibrous crystals. It is opaque but a little translucent when the magnesium content is high. It has the Mohs hardness of 5.5-6 and density of 3.6-4.7 g/cm^3 (the density increases with the iron content increasing).

Table4-8 the EDS analysis results of chemical composition of vonsenite*

Measuring Point	Chemical composition %

Note: * represents that the results are a little higher than the actual value because the element B can not be detected by EDS.

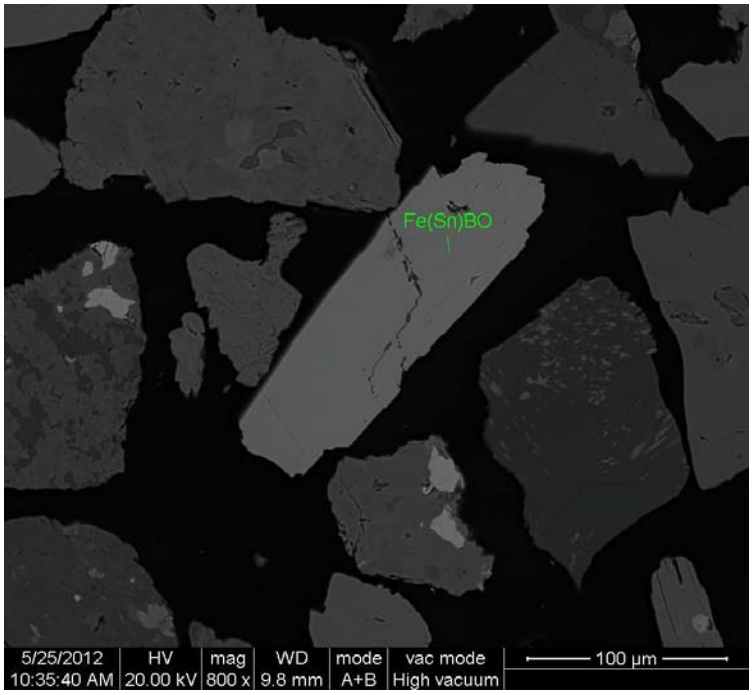

Photo 20 SEM to magnify 800 times
The Sn-rich vonsenite appears as long columnar crystals.

Most of vonsenite in the sample appears as monomer, some is rich in tin (see photo 20) and some is mixed with a small amount of biotite and vesuvianite (see photos 21, 22).

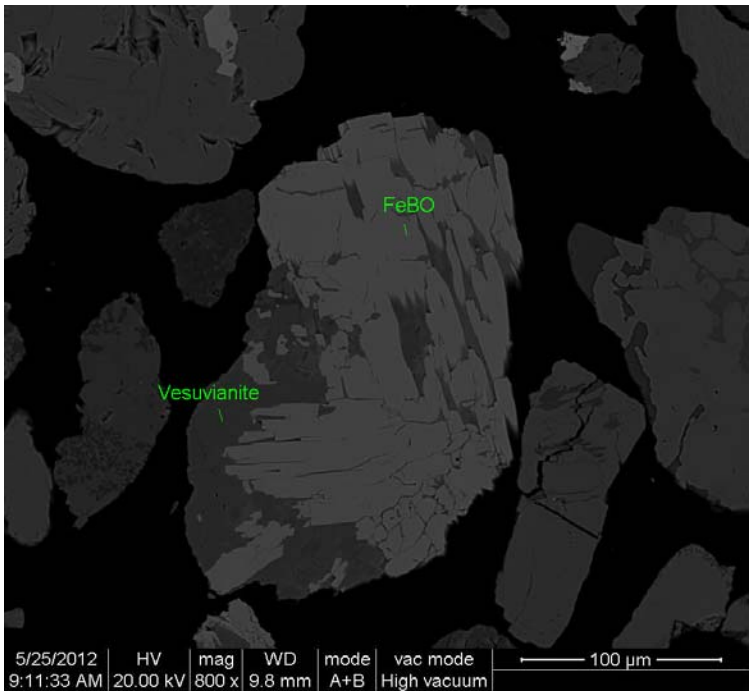

Photo 21 SEM to magnify 800 times
Vonsenite as fibrous aggregates is intergrown with vesuvianite.

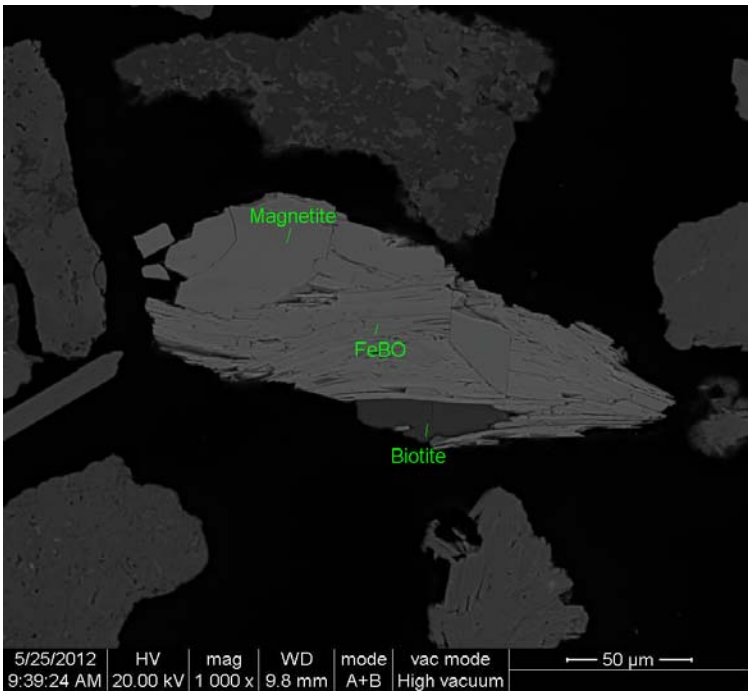

Photo 22 SEM to magnify 1000 times
Vonsenite as fibrous aggregates is intergrown with magnetite and biotite.

4.1.6.6 Stokesite $Ca_2Sn_2(H_2O)_4[Si_6O_{18}]$

There is a trace of stokesite in this sample which is often intergrown with quartz. The theoretical chemical composition of stokesite is: CaO 13.25%, SnO_2 35.65%, SiO_2 42.58%, H_2O 8.52%. According to the EDS analysis results of chemical composition shown in Table 9, this stokesite contains a small amount of iron and the Sn content is a little lower. It appears as irregularly granular or tabular, has the Mohs hardness of 6 and density of 3.18 g/cm^3.

Table4- 9 the EDS analysis results of chemical composition of stokesite*

Measuring Point	Chemical composition %			
	CaO	SnO_2	FeO	SiO_2
1	14.25	34.51	1.87	49.37
2	16.38	34.59	0.00	49.03
3	15.75	34.80	1.48	47.97
Average value	15.46	34.63	1.12	48.79

Note: * represents that the results are a little higher than actual value because the element H cannot be detected by EDS.

4.1.6.7 Gangue minerals

The gangue minerals of this sample mainly are biotite and amphibole, followed by vesuvianite, pyroxene, andradite, calcite, quartz, feldspar, chlorite, etc..

4.1.7. Occurrence of tungsten

According to the results of quantitative measurement, the EDS analysis results and the chemical analysis results of pure minerals, the distribution of tungsten in the minerals is shown in Table 4-10. Based on Table4-10,

tungsten mainly exists in the form of scheelite in this sample. The tungsten of scheelite makes up of 91.12% of total tungsten; the tungsten of wolframite accounts for 3.23%; the tungsten contained in the sulfide minerals (including pyrrhotite, pyrite, arsenopyrite, loellingite, chalcopyrite, stannite, sphalerite and bismuth) occupies 0.82%; the tungsten still occurred in the gangue minerals accounts for 4.82% at the fineness of 100%-0.045mm. So the highest recovery of tungsten is about 94%. If only scheelite is recovered, the theoretical recovery of tungsten will be about 91%.

Table4-10 the distribution of tungsten in the minerals (the pure minerals are finally purified at the fineness of 100%-0.045mm)

Mineral	Abundance of mineral %	Assay WO_3 %	Distribution %
Scheelite	0.243	79.59	91.12
Wolframite	0.009	76.24	3.23
Sulfide minerals	1.164	0.15	0.82
Gangue minerals	85.242	0.010	4.82
Others	13.342	/	/
Total	100.000	0.212	100.00

4.1.8 Summary

(1) The metallic minerals can be recovered in this sample include scheelite, cassiterite, a small amount of vonsenite, magnetite and siderite; other metallic minerals include a small amount of pyrite, chalcopyrite, sphalerite, etc.. The gangue minerals of this sample mainly are biotite and amphibole, followed by vesuvianite, garnet, quartz, calcite, etc..

(2) The ratio of scheelite to wolframite is 27 to 1 and the tungsten of

wolframite accounts for about 3% of total tungsten. So it is feasible to only recover the scheelite and the beneficiation process will be simplified.

(3) The results of mineral grain size distribution indicate that the grain size of scheelite is uneven and the size range is extensive; each size fraction is almost equal in amount. The scheelite grains less than 0.01mm account for more than 25% in which the grains less than 0.005mm occupy 15%. Obviously, the scheelite is over-ground. The grain size of cassiterite is even with the main size range of 0.01~0.16mm, the amount of micro-fine size fraction of which is far less than that of scheelite.

(4) The results of liberation degree of scheelite and cassiterite indicate that the dissociation of scheelite is good while the liberation degree of cassiterite is low especially in the coarse size fraction. The liberation degree of scheelite is up to 89.08% while that of cassiterite is only 53.72% at the grinding fineness of 72.56%-0.075mm.

(5) The occurrence of tungsten indicates that tungsten mainly exists in the form of scheelite in this sample. The tungsten of scheelite makes up of 91.12% of total tungsten; the tungsten of wolframite accounts for 3.23%; the tungsten contained in the sulfide minerals (including pyrrhotite, pyrite, arsenopyrite, loellingite, chalcopyrite, stannite, sphalerite and bismuth) occupies 0.82%; the tungsten still occurred in the gangue minerals accounts for 4.82% at the fineness of 100%-0.045mm. So the highest

recovery of tungsten is about 94%. If only scheelite is recovered, the theoretical recovery of tungsten will be about 91%.

(6) The occurrence of tin is complex. Tin mainly occurs in the form of cassiterite. Other tin minerals or tin-bearing minerals include stannite, tin-bearing vonsenite and a trace of stokesite.

4.2 Study on process mineralogy of VM2S sample

4.2.1 Chemical composition of sample

The results of multi-elemental analysis of the sample are shown in Table 10.

Table 4.10 Results of multi-elemental analysis

Elements	WO_3	Sn	Fe	Mo	Ca	SiO_2	K_2O
Abundance %	0.48	0.20	20.10	<0.01	10.71	35.20	3.43
Elements	MgO	Mn	As	S	Cu	Al_2O_3	Na_2O
Abundance %	2.37	0.30	0.11	0.49	0.02	8.03	0.62

4.2.2 Mineral composition of sample

The mineral composition of sample was determined and quantitatively measured by optical microscope and MLA. According to the results shown in Table 4-11, tungstate minerals are dominated by scheelite with a very small amount of wolframite and the ratio of scheelite to wolframite is 38 to 1; tin minerals mainly are cassiterite and a trace of stokesite, and vonsenite also contains tin. Compared with the sample VMMS, the scheelite abundance of this sample is higher, the cassiterite abundance is lower, and this sample contains no stannite. Sulfide minerals are of great varieties but only a small amount with a total of about 1% and include pyrrhotite, pyrite, a trace of chalcopyrite, chalcocite, arsenopyrite, etc.; iron oxide minerals include magnetite, siderite, vonsenite, a small amount of ilmentite, limonite, rutile, etc.; gangue minerals are dominated by

biotite and amphibole, followed by vesuvianite, quartz, calcite, chlorite, andradite, pyroxene, feldspar, etc..

Table 4-11 Results of quantitative measurement

Mineral	Abundance %	Mineral	Abundance %	Mineral	Abundance %
Scheelite	0.605	Siderite	2.947	Titanite	0.684
Wolframite	0.002	Quartz	4.402	Calcite	3.897
Cassiterite	0.234	Feldspar	0.823	Ankerite	0.098

Magnetite	0.791	Tourmaline	0.099	Others	0.046
Limonite	0.113	Topaz	0.023	Total	100.000

4.2.3 Mineral grain size distribution

The grain size distribution shown in Table4-12 indicates that the grain size of scheelite is uneven and the size range is extensive. The scheelite grains less than 0.01mm account for about 20% in which the grains less than 0.005mm occupy 12%. The scheelite is over-ground. The grain size of cassiterite is even with the main size range of 0.01~0.16mm, and the cassiterite grains less than 0.01mm are minor portion.

Table 4-12 the grain size distribution of scheelite and cassiterite

Size mm	Mineral grain size distribution %	
	Scheelite	Cassiterite
-0.16+0.08	18.51	21.65
-0.08+0.04	23.15	29.92

4.2.4 Mineral liberation

The liberation degree of scheelite and cassiterite in each size fraction was measured and the results are shown in Table 4-13. Based on the results, the dissociation of scheelite is good while the liberation degree of cassiterite is low. The liberation degree of scheelite is up to 90.02% while that of cassiterite is only 75.76% at the grinding fineness of 71.44%-0.075mm. Compared with the sample VMMS, the liberation degree of scheelite of this sample is almost equal, but the liberation degree of cassiterite is obviously higher.

Table 4-13 the liberation degree of scheelite and cassiterite

4.2.5 Physical and chemical properties and dissemination state of minerals

4.2.5.1 Scheelite Ca(WO_4)

Scheelite is the main mineral recovered and the abundance is 0.605%. Its crystals appear as tetragonal dipyramid or equiaxed granular, colorless and transparent. The scheelite of tungsten concentrate appears as crushed granular, oily luster, medium hardness (4.5), density 5.8-6.2g/cm^3, brittle and a clear cleavage. According to the Energy-dispersive X-ray spectroscopy ("EDS" for short) analysis results of chemical composition shown in Table 4-14, the scheelite in this sample generally contains a small number of irons and the molybdenum content is too low to be detected by EDS; the average WO_3 content is 79.16%. The chemical analysis results of pure scheelite are: WO_3 79.12%, Mo 0.068%.

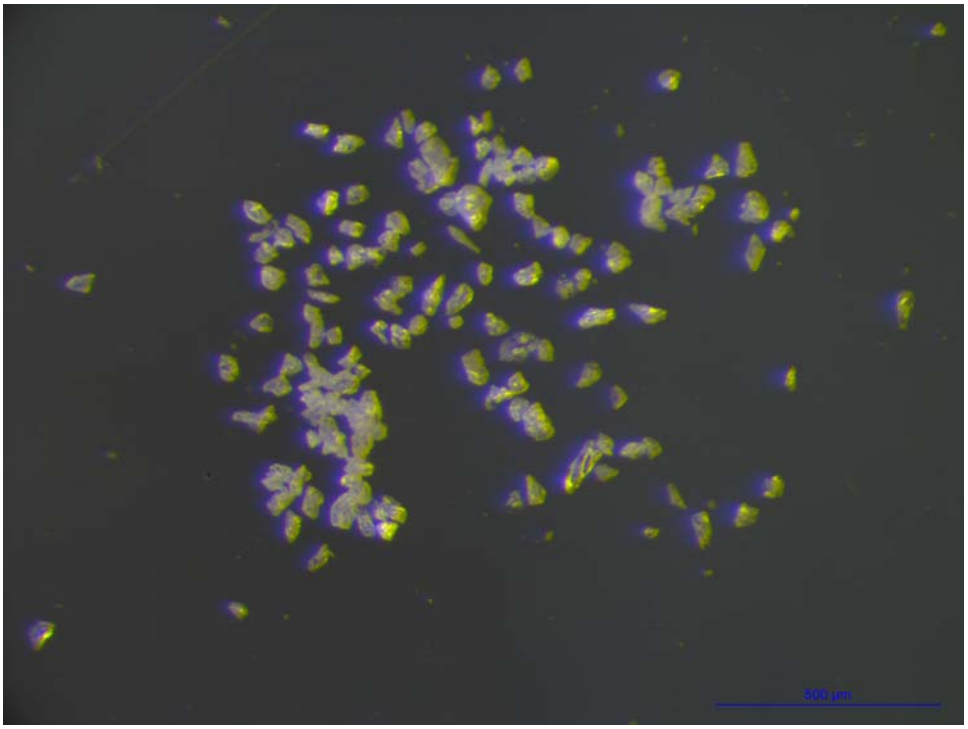

Photo 1 Stereomicroscope to magnify 50 times
Scheelite particles

The scheelite of sample exists in the following forms: ① most of scheelite is monomer and rare scheelite still includes the residual wolframite of metasomatism (see photos 2, 3); ② scheelite includes the micro-fine gangue minerals such as biotite, fluorite, etc. (see photos 4, 5); ③ scheelite is intergrown with the gangue minerals such as amphibole, calcite, vesuvianite, etc.(see photos 6, 7, 8); ④micro-fine scheelite is included in the gangue minerals such as biotite, fluorite, amphibole, etc. (see photos 9, 10, 11).

4.2.5.2 Wolframite $(MnFe)WO_4$

The abundance of wolframite is only 0.002%. Wolframite crystals usually appear as thick tabular or short prismatic. The color changes with the content of iron and manganese. The higher content of iron it contains, the darker color it is. It has the hardness of 4-5.5 and density of 7.18-7.51g/cm^3 which also increases with the iron content increasing. The wolframite which is rich in iron has weak magnetism. The wolframite in this sample is rare. Fine wolframite aggregates are occasionally seen and the gaps among grains are filled with fluorite (see photo 12). Sometimes wolframite as residual crystal is included in scheelite. According to the EDS analysis results of chemical composition shown in Table 4-15, this wolframite generally contains a small amount of Ca and the Mn content is low, which belongs to ferberite.

Table 4-15 the EDS analysis results of chemical composition of wolframite

Measuring Point	Chemical composition %

4.2.5.3 Cassiterite SnO_2

The abundance of cassiterite is 0.234%. According to the EDS analysis results of chemical composition shown in Table 4-16, the cassiterite of this sample generally contains a few impurities of Fe and Si; the average Sn content is 78.27%. Cassiterite appears as brown to black colors, adamantine luster. It is brittle and has the Mohs hardness of 6-7 as well as density of 6.8-7.0g/cm^3. Generally, cassiterite is non-magnetic, but the cassiterite bearing iron has weak magnetism. Most of cassiterite appears as monomer (see photo 11). Besides, cassiterite is closely related to biotite. There is often cassiterite intergrowing with biotite (see photo 13), also cassiterite including the micro-fine inclusions such biotite,

amphibole, etc.(see photos 14, 15). Rare micro-fine cassiterite is included in the gangue minerals such as biotite, quartz, etc.(see photo 16).

4.2.5.4 Ludwigite-vonsenite $(Mg, Fe)_2Fe^{3+}[BO_3]O_2$

It is completely isomorphous between Mg and Fe^{2+} in the composition of ludwigite- vonsenite. It can be divided into ludwigite and vonsenite in accordance with $Mg>Fe^{2+}$ or $Mg<Fe^{2+}$. Based on the EDS analysis results of chemical composition are shown in Table 4-17, the vonsenite is rich in Fe and poor in Mg and generally contains Sn with the Sn content between 0.1% and 5%. Vonsenite appears as dark green to balck colors (the color becomes dark with the iron content increasing), light greenish black to black streak, dim luster but silky luster on the fresh surface of fibrous crystals. It is opaque but a little translucent when the magnesium content is high. It has the Mohs hardness of 5.5-6 and density of 3.6-4.7 g/cm^3 (the density increases with the iron content increasing).

Table 4-17 EDS analysis results of chemical composition of vonsenite*

Measuring Point	Chemical composition %

14	65.84	1.49	0.86	0.39	0.55	0.27	0.28	30.32
15	61.77	3.90	0.98	0.40	0.16	0.07	0.47	32.25
Average value	65.76	1.01	0.85	0.26	0.17	0.18	0.82	30.94

Note: * represents that the results are a little higher than the actual value because the element B can not be detected by EDS.

4.2.5.5 Stokesite $Ca_2Sn_2(H_2O)_4[Si_6O_{18}]$

There is a trace of stokesite in this sample which is often intergrown with quartz. The theoretical chemical composition of stokesite is: CaO 13.25%, SnO_2 35.65%, SiO_2 42.58%, H_2O 8.52%. According to the EDS analysis results of chemical composition shown in Table 4-18, this stokesite contains a small amount of iron and the Sn content is a little lower. It appears as irregularly granular or tabular, has the Mohs hardness of 6 and density of 3.18 g/cm^3.

Table4-18 EDS analysis results of chemical composition of stokesite*

Measuring Point	Chemical composition %			
	CaO	SnO_2	FeO	SiO_2
1	16.26	34.55	1.22	47.97
2	16.11	34.95	1.15	47.79
Average value	16.19	34.75	1.19	47.88

Note: * represents that the results are a little higher than actual value because the element H cannot be detected by EDS.

4.2.5.6 Gangue minerals

The gangue minerals of this sample mainly are biotite and amphibole, followed by vesuvianite, quartz, calcite, chlorite, andradite, pyroxene, feldspar, etc..

4.2.6 Occurrence of tungsten

According to the results of quantitative measurement, the EDS analysis results and the chemical analysis results of pure minerals, the distribution of tungsten in the minerals is shown in Table 4-19. Based on Table 10, tungsten mainly exists in the form of scheelite in this sample. The tungsten of scheelite makes up of 97.00% of total tungsten; the tungsten of wolframite accounts for 0.31%; the tungsten contained in the sulfide minerals (including pyrrhotite, pyrite, arsenopyrite, loellingite, chalcopyrite, sphalerite and bismuth) occupies 0.23%; the tungsten still occurred in the gangue minerals accounts for 2.46% at the fineness of 100%-0.045mm. So the theoretical recovery of tungsten is about 97%.

Table 4-19 the distribution of tungsten in the minerals (the pure minerals are finally purified at the fineness of 100%-0.045mm)

Mineral	Abundance of mineral %	Assay WO_3 %	Distribution %
Scheelite	0.605	79.12	97.00
Wolframite	0.002	76.17	0.31
Sulfide minerals	1.464	0.078	0.23
Gangue minerals	93.192	0.013	2.46
Others	4.737	/	/
Total	100.000	0.493	100.00

4.2.7 Summary

(1) The metallic minerals can be recovered in this sample include scheelite, cassiterite, a small amount of vonsenite, magnetite and siderite; other metallic minerals include a small amount of pyrite, chalcopyrite, sphalerite, wolframite, etc.. The gangue minerals of this sample mainly are biotite and amphibole, followed by vesuvianite, quartz, calcite, chlorite, etc..

(2) The ratio of scheelite to wolframite is 38 to 1 and the tungsten of wolframite accounts for about 0.3% of total tungsten. So it is feasible to only recover the scheelite and the beneficiation process will be simplified.

(3) The grain size of scheelite is uneven and the size range is extensive. The scheelite grains less than 0.01mm account for about 20% in which the grains less than 0.005mm occupy 12%. The scheelite is overground. The grain size of cassiterite is even with the main size range of 0.01~0.16mm, and the cassiterite grains less than 0.01mm is minor

portion.

(4) The results of liberation degree of scheelite and cassiterite indicate that the dissociation of scheelite is good while the liberation degree of cassiterite is low. The liberation degree of scheelite is up to 90.02% while that of cassiterite is only 75.76% at the grinding fineness of 71.44%-0.075mm. Compared with the sample VMMS, the liberation degree of scheelite of this sample is almost equal, but the liberation degree of cassiterite is obviously higher.

(5) The occurrence of tungsten indicates that tungsten mainly exists in the form of scheelite in this sample. The tungsten of scheelite makes up of 97.00% of total tungsten; the tungsten of wolframite accounts for 0.31%; the tungsten contained in the sulfide minerals (including pyrrhotite, pyrite, arsenopyrite, loellingite, chalcopyrite, sphalerite and bismuth) occupies 0.23%; the tungsten still occurred in the gangue minerals accounts for 2.46% at the fineness of 100%-0.045mm. So the theoretical recovery of tungsten is about 97%.

(6) The occurrence of tin is complex. Tin mainly occurs in the form of cassiterite. Other tin minerals or tin-bearing minerals are tin-bearing vonsenite and stokesite.

5 Mineral processing tests

5.1 Principle flow-sheet

As the sulfide minerals and magnetite were already comprehensively recovered or rejected in Australia using sulfide flotation and LIMS after sample's being ground to P_{80}-120 micron, the contract requires to carry out lab test and to gains the scheelite concentrate which meets the quality requirements with reasonable higher recovery and to remain the cassiterite in tailings as much as possible.

According to the dressing practice of scheelite ores at home and abroad, the coarse-grained scheelite is recovered mainly by means of gravity separation, while the fine-grained by flotation primarily. The scheelite minerals in the ore are liberated basically in the size fraction of 80% -0.12mm, so it is suitable to recover by flotation.

The single scheelite flotation mainly adopts fatty acids collector or modified fatty acids collector at present, while the gangue minerals bearing calcium such as fluorite, calcite, diopside, garnet, and other gangue minerals such as biotite, amphibole, andradite，etc. they also have good floatability. The usual regulator and their combination are: sodium carbonate-sodium silicate, caustic soda-sodium silicate, sodium carbonate-caustic soda-sodium silicate, sodium carbonate-lime-sodium silicate、lime-sodium silicate, etc. The combined regulator of sodium

carbonate-sodium silicate is adopted in our scheelite roughing process. The new reagent GYWA developed by GZRINM is used as scheelite flotation collector, replacing the current sodium oleate and 731 collector whose selectivity is poorer and consumption is higher.

The rougher concentrate of scheelite flotation still contains many gangue minerals bearing calcium such as fine-grained fluorite, calcite, diopside，hedenbergite, garnet, andradite, etc. The floatability of gangue minerals bearing calcium is more similar to that of scheelite after their interaction with fatty acids collector, so the cleaning separation is very difficult. The so called “Petrov Method” is used in some dressing plant. The key of the method is: ⑴ strong attrition of high density pulp with large amount of sodium silicate at elevated temperature (normally 90^{o}C); □ heated pulp is dewatered several times prior to being sent for further flotation. But for many kinds of refractory scheelite ores, this method is not very good. So in recent years, to deal with this situation the traditional “Petrov Method” has been improved by GZRINM through serials of research work and practice. The innovation is that besides of large amount of sodium silicate, a new combination of reagents is added in the attrition process at elevated temperature and without dewatering, which intensifies the depression for gangue minerals, especially for calcite and fluoride, sulfide minerals, eliminates the operation of dilution and reagent-removing and directly floats scheelite from heated pulp, hence a quite good index is achieved，

the tests of heated cleaning process are mainly selected to conduct further.

5.2 Magnetic separation

The trial test of adoption of WHGMS in roughing was conducted to reject lots of paramagnetic gangue minerals in ore aiming to upgrade the head with lower loss of tungsten and tin, hence benefiting the subsequent flotation. Several technological factors such as magnetic field intensity and matrix diameter and combination of different diameter matrix are tested, but the results are not satisfactory, as a quite amount of scheelite and cassiterite minerals are lost in the Mags fraction. The test flow-sheet is shown in Fig. 5-1, with the related results shown in Table 5-1 and Table 5-2.

In order to further determine the loss of WO3 and Sn in magnetic product, take 1 Mgs in Table5-1 and 2 Mgs in Table5-2 as the feed and send them to grind separately with fine grinding fineness and conduct WHGMS tests, the corresponding test results are shown in Table5-3 and Table5-4 separately. So it is indicated that quite a few of Sn and part of tungsten minerals are still lost in magnetic fraction. So it is indicated that

WHGMS is not suitable for Main Skarn Sample and 2# Skarn Sample.

6 Mineral Processing Test for Main Skarn Ore

6.1 Primary calcite rougher and cleaner flotation

The major task of primary calcite rougher and cleaner flotation is to float out most of scheelite and calcite as well as fluorite and meanwhile to remain majority of tin minerals in tailings, hence to create favorable condition for tin minerals recovery.

6.1.1 Preliminary test on primary calcite rougher flotation

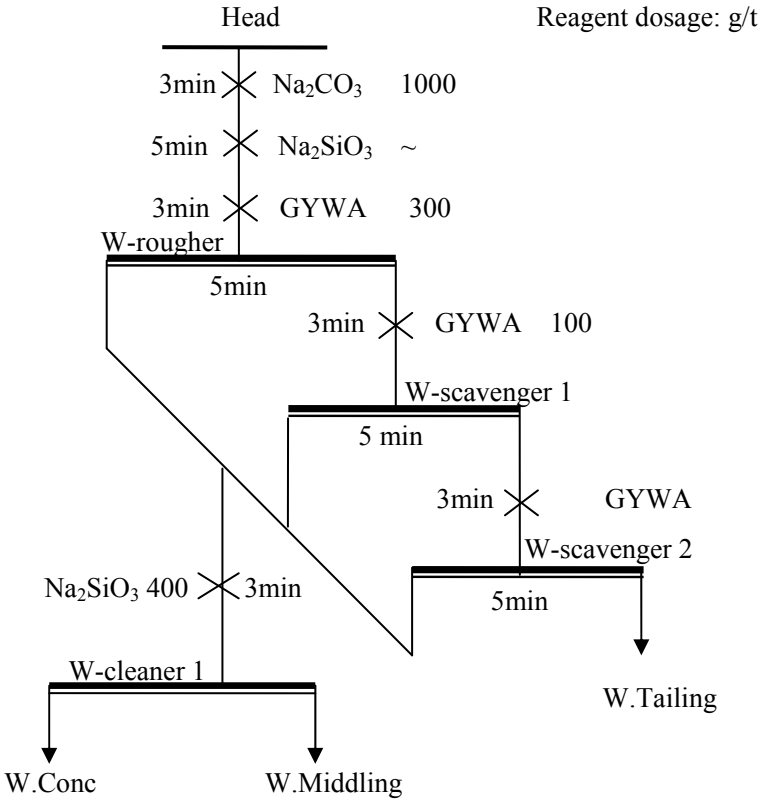

Fig6.1 Flow-sheet of primary calcite rougher

Preliminary test on primary calcite rougher flotation is conducted by the flow-sheet in Fig. 6.1 with its results in Table 6.1. It is indicated that good result can be achieved in both cases, but result of Na_2SiO_3 2000 is better.

6.1.2 Tests of selection of collector types for W-rougher

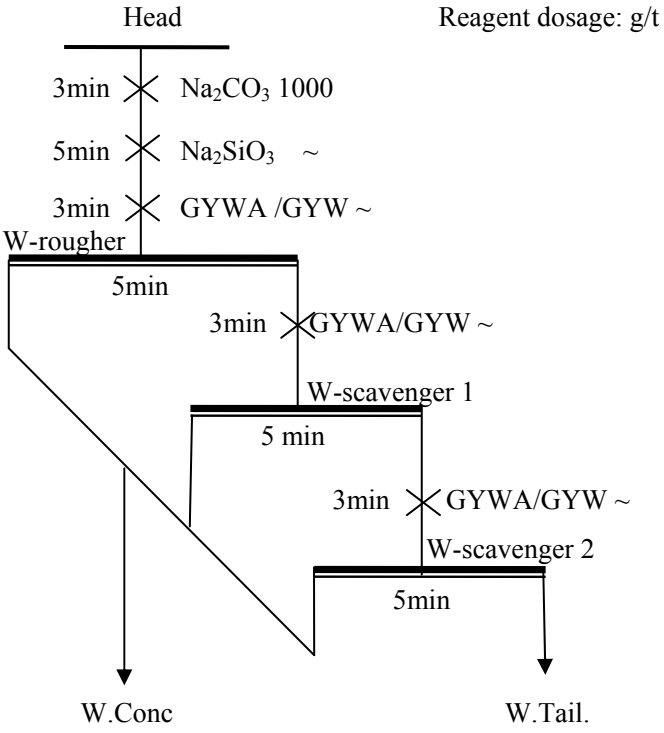

Fig6.2 Flow-sheet of selection of collector for primary calcite rougher

The test on comparison of different collector at different dosage of sodium silicate is conducted by the flow-sheet in Fig.6.2 and with flotation regime and test result are shown in Table 6-2 and Table 6-3, respectively. It is indicated that GYW and GYWA have basically similar performance. GYWA (320+120g/t) is selected in view of convenience when 2000g/t Na_2SiO_3 is added.

6.1.3 Tests on regulators for primary calcite rougher

The comparison test of regulators (Na_2CO_3 and NaOH) for primary calcite rougher is conducted with its flow-sheet in Fig.6-3 and reagent regime and test result in Table6-4 and Table 6-5. It is indicated that Na_2CO_3 1000g/t is more suitable

6.1.4 Dosage test of Na_2SiO_3 and GYWA for primary calcite rougher

As the dosage of Na_2SiO_3 and GYWA will affect each other, so the dosage tests of Na_2SiO_3 and GYWA for primary calcite rougher are conducted by the flow-sheet in Fig.6-4 with its reagent regime and test result in Table 6-6 and Table 6-7. It is indicated that good results can be achieved when Na_2SiO_3 2000g/t and GYWA 320+160+80 g/t are used. It is potential to reduce the dosage of collector further.

6.1.5 Test of pulp density for primary calcite rougher

Normally, the density of pulp affects flotation in a certain extent. The test of pulp density for primary calcite rougher is conducted according to the flow-sheet shown in Fig. 6.5 with its test result in Table 6-8. It is indicated that good results can be achieved when density of pulp of rougher is ranging between 30~48%, but the result is better when density of pulp is around 37%.

6.1.8 The locked cycle test for primary calcite rougher

The locked cycle test for primary calcite rougher is conducted on the basis of open circuit test by the flow-sheet in Fig.6-8 and with its result in Table 6-11. It is indicated that the test result is quite good, the scheelite recovery is high with majority of tin minerals remain in tails. The tails **(M2)** is sent for process mineralogy study with its mineralogical result in

Appendix 1.

6.3 Scheelite cleaner flotation

Taking the W-Conc. got from Fig. 6.9 as the feed for scheelite cleaner flotation, after thickening of pulp to about density 65%, following batch tests are conducted to determine suitable parameters for scheelite cleaner flotation.

6.3.1 Test on Na_2SiO_3 dosage for Conc. from rougher flotation

Test on Na_2SiO_3 dosage for Conc. from scheelite rougher flotation is conducted by the flow-sheet in Fig.6.10 with the test result in Table 6-13.

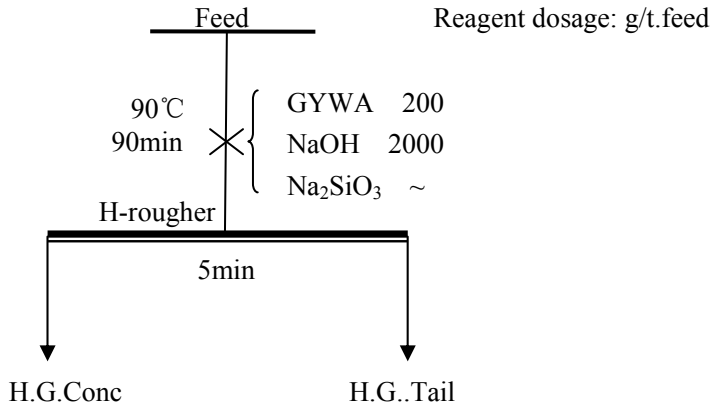

Fig 6.10. Flow-sheet of heated flotation for VMMS

Table 6-13 Test on sodium silicate dosage of heated flotation for VMMS

Dosage, g/t.feed	Product	Wt.%	Assay,WO_3%	Recovery, WO_3%
30000	H.G.Conc	7.12	37.57	85.97
	H.G.Tail	92.88	0.47	14.03
	Feed	100.00	3.11	100.00

	H.G.Tail	95.82	0.82	25.62
	Feed	100.00	3.07	100.00

It is indicated that when sodium silicate dosage is 50000g/t.feed, the result is better.

6.3.2 Test on NaOH dosage of heated flotation for VMMS

In our improved “Petrov Method”, the NaOH is used to intensify the depression on gangue minerals, especially on calcium-bearing gangue minerals. Test on NaOH dosage for Conc. from scheelite rougher

flotation is conducted by the flow-sheet shown in Fig.6.11 with the test result in Table 6-14.

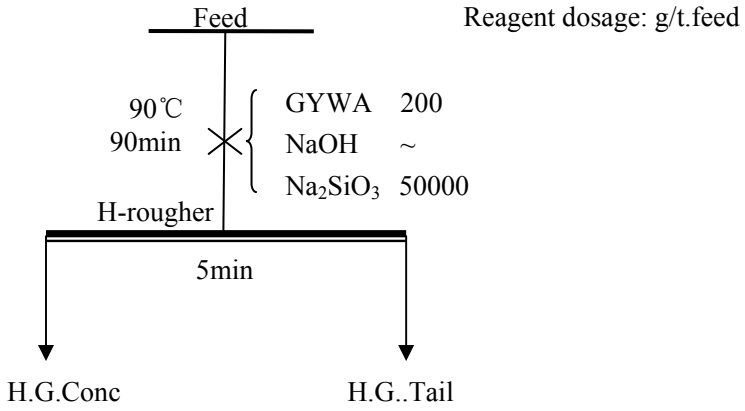

Fig 6.11. Flow-sheet of Heated flotation for VMMS

Table 6-14 Test on NaOH dosage of heated flotation for VMMS

Dosage, g/t.feed	Product	Wt.%	Assay,WO_3%	Recovery,WO_3%
0	H.G.Conc	6.57	39.37	85.49
	H.G.Tail	93.43	0.47	14.51
	Feed	100.00	3.03	100.00

	H.G.Tail	95.18	0.69	21.21
	Feed	100.00	3.10	100.00

It is indicated that suitable dosage of sodium hydroxide is helpful for upgrading concentrate, when sodium hydroxide dosage is 2000g/t.feed, the result is better.

6.3.3 Test on pulp temperature and heating time for heated flotation

In our improved "Petrov Method", normally, the heating temperature and the time of heating (Time for warm-keeping) will affect the separation performance. The test on pulp temperature and heating time for heated flotation are conducted by the flow-sheet shown in Fig.6.12 with the test results in Table 6-15. It is indicated that better results can be achieved when heating temperature is 90℃ and time of heating (Time for warm-keeping) is 90 minutes.

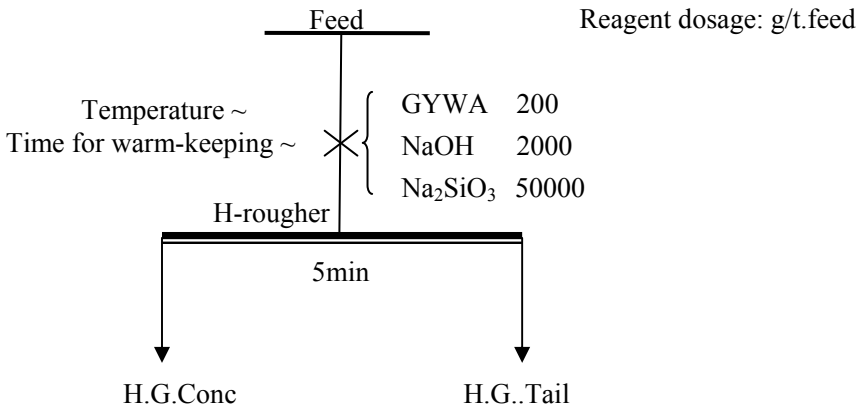

Fig 6.12. Flow-sheet of heated flotation for VMMS

Table 6-15 Test on pulp temperature and heating time of heated flotation

6.6 Gravity regrind mill

According to the requirement, the products of Tail1 + Mid2,2 + Tail 2 from flow-sheet 6-17 will be reground to P_{80} -0.040mm and will be combined together with the overflow from hydraulic classifier to be the feed for further secondary calcite rougher flotation

6.7 Secondary calcite rougher flotation

The feed as shown in Table 6-23 for secondary calcite rougher flotation comprises Tail1 + Mid2.2 + Tail2 from flow-sheet in Fig. 6.17 (reground to P80 -0.040mm) and the overflow from hydraulic classifier in Fig. 6.16.

The Screen analysis of feed sample for secondary calcite rougher flotation is presented in Table 6-24.It is indicated that for VMMS sample, in the combined feed for secondary calcite rougher flotation, the tungsten and tin minerals are mostly distributed in -0.030mm fraction. Also, the chemical analysis of major elements of feed sample is shown in Table 6-25.

It is indicated that for VMMS sample, when only regulator of sodium silicate is added, the tin recovery in tailings is higher and meanwhile the calcite content in concentrate is also higher. So, only sodium silicate is recommended to be added in the locked cycle test.

In secondary calcite cleaner flotation, only a small amount of sodium silicate 300g/t.feed is added.

6.8 Locked cycle test for secondary calcite flotation

The locked cycle test flow-sheet for secondary calcite (rougher $ cleaner) flotation is shown in Fig. 6-19 with the corresponding test result presented in Table 6-28. It is indicated that through secondary calcite flotation, most of calcite and part of fluoride are rejected, hence creating favorable condition for subsequent tin slime recovery. The two products from the test: secondary calcite concentrate **(M4)** and secondary calcite tail **(M3)** are sent for process mineralogy study with their results presented in appendix 1.

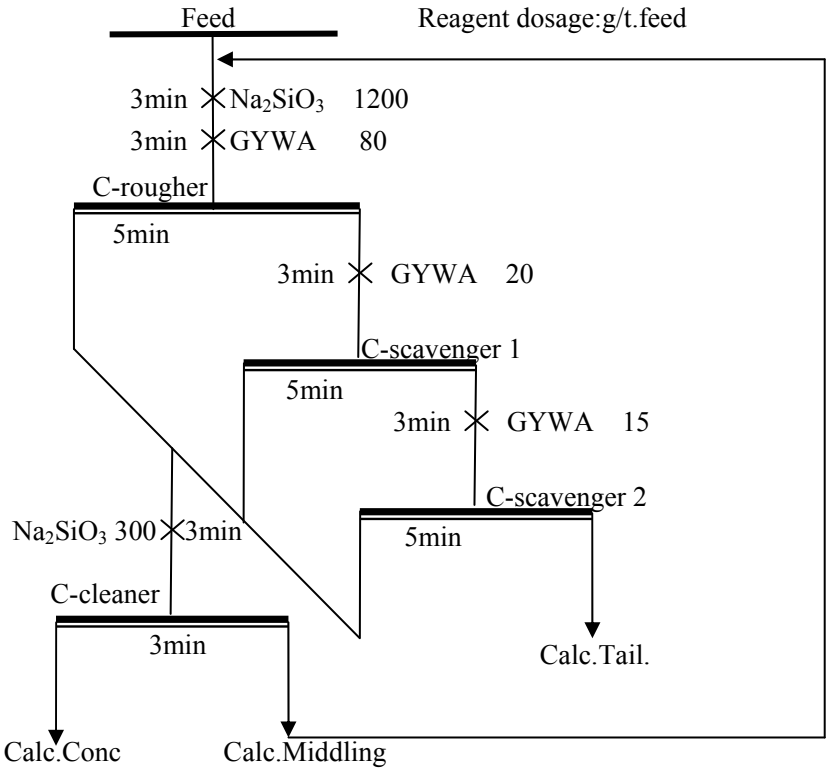

Fig 6.19 Locked cycle test for secondary calcite rougher flotation

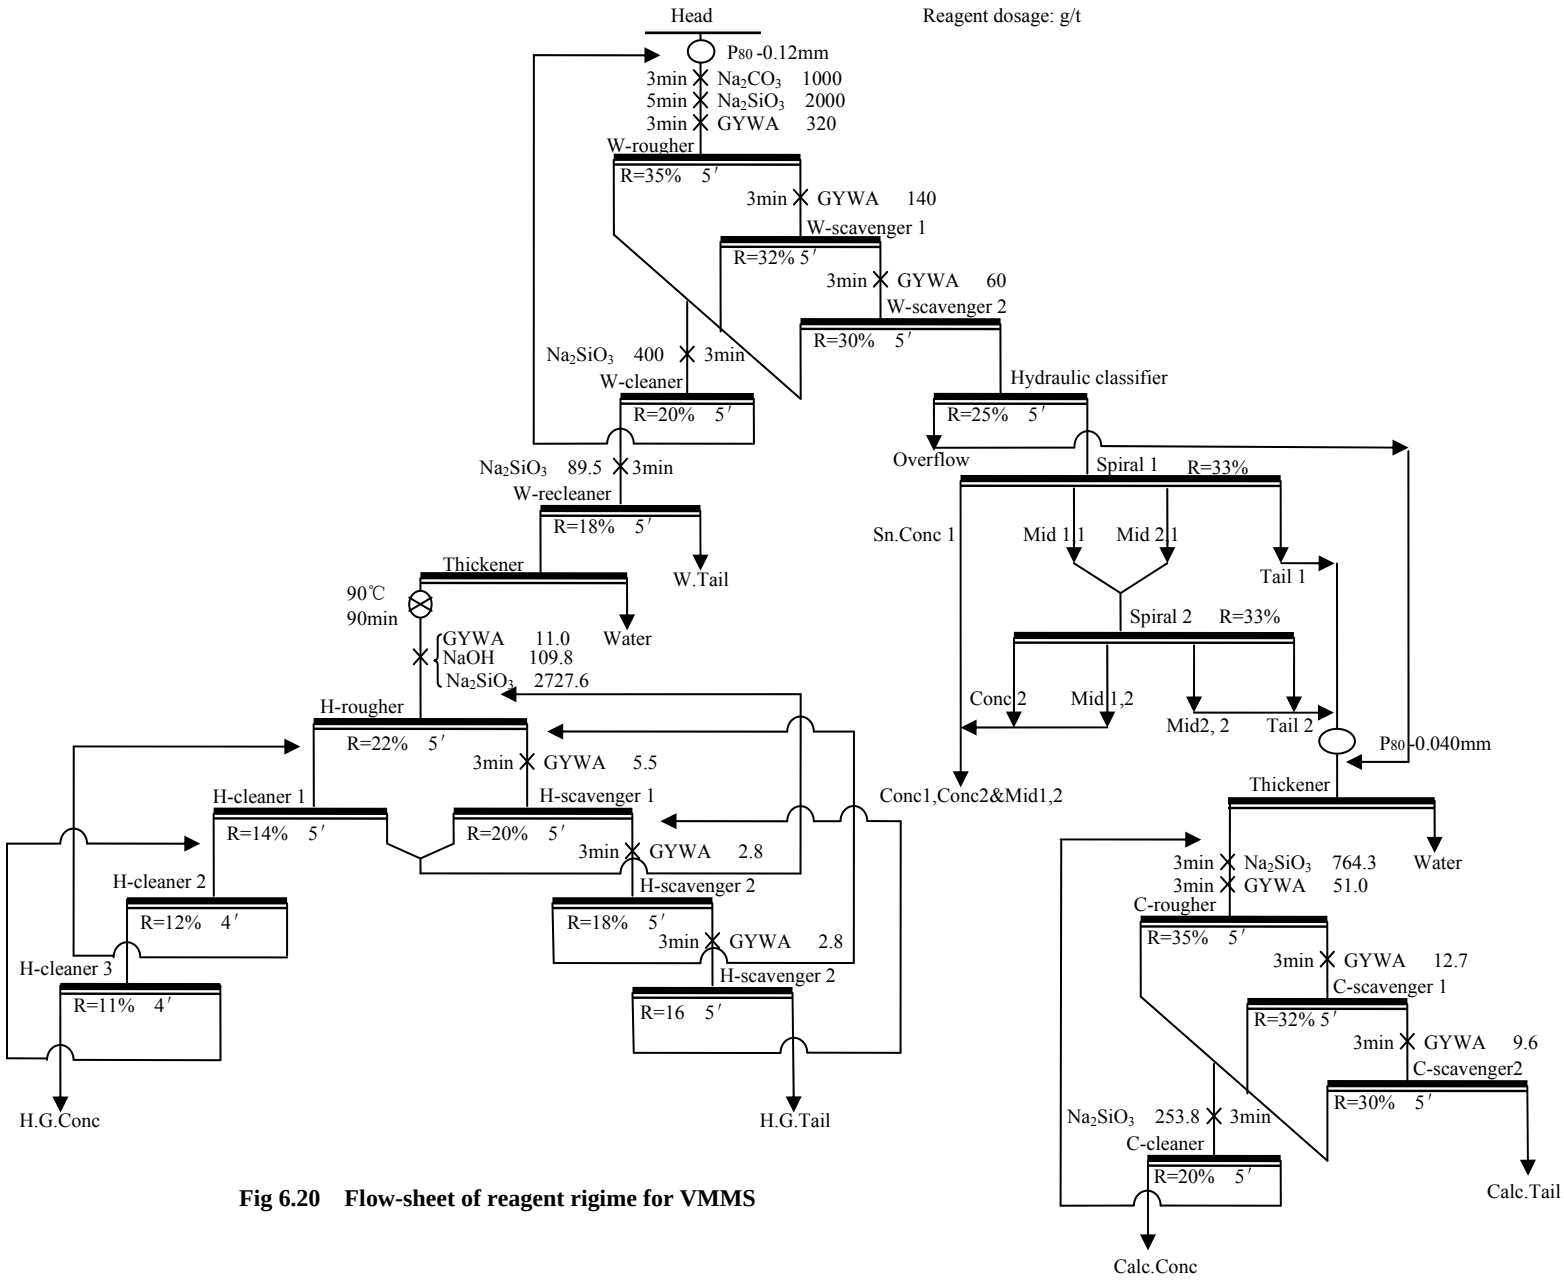
6.9 The whole quantitative flow-sheet and the flow-sheet of reagent regime for VMMS

On the basis of al above tests for VMMS, to summarize, the flow-sheet of reagent regime for VMMS is presented in Fig.6.20. The whole quantitative flow-sheet for VMMS is presented in Fig.6.21.



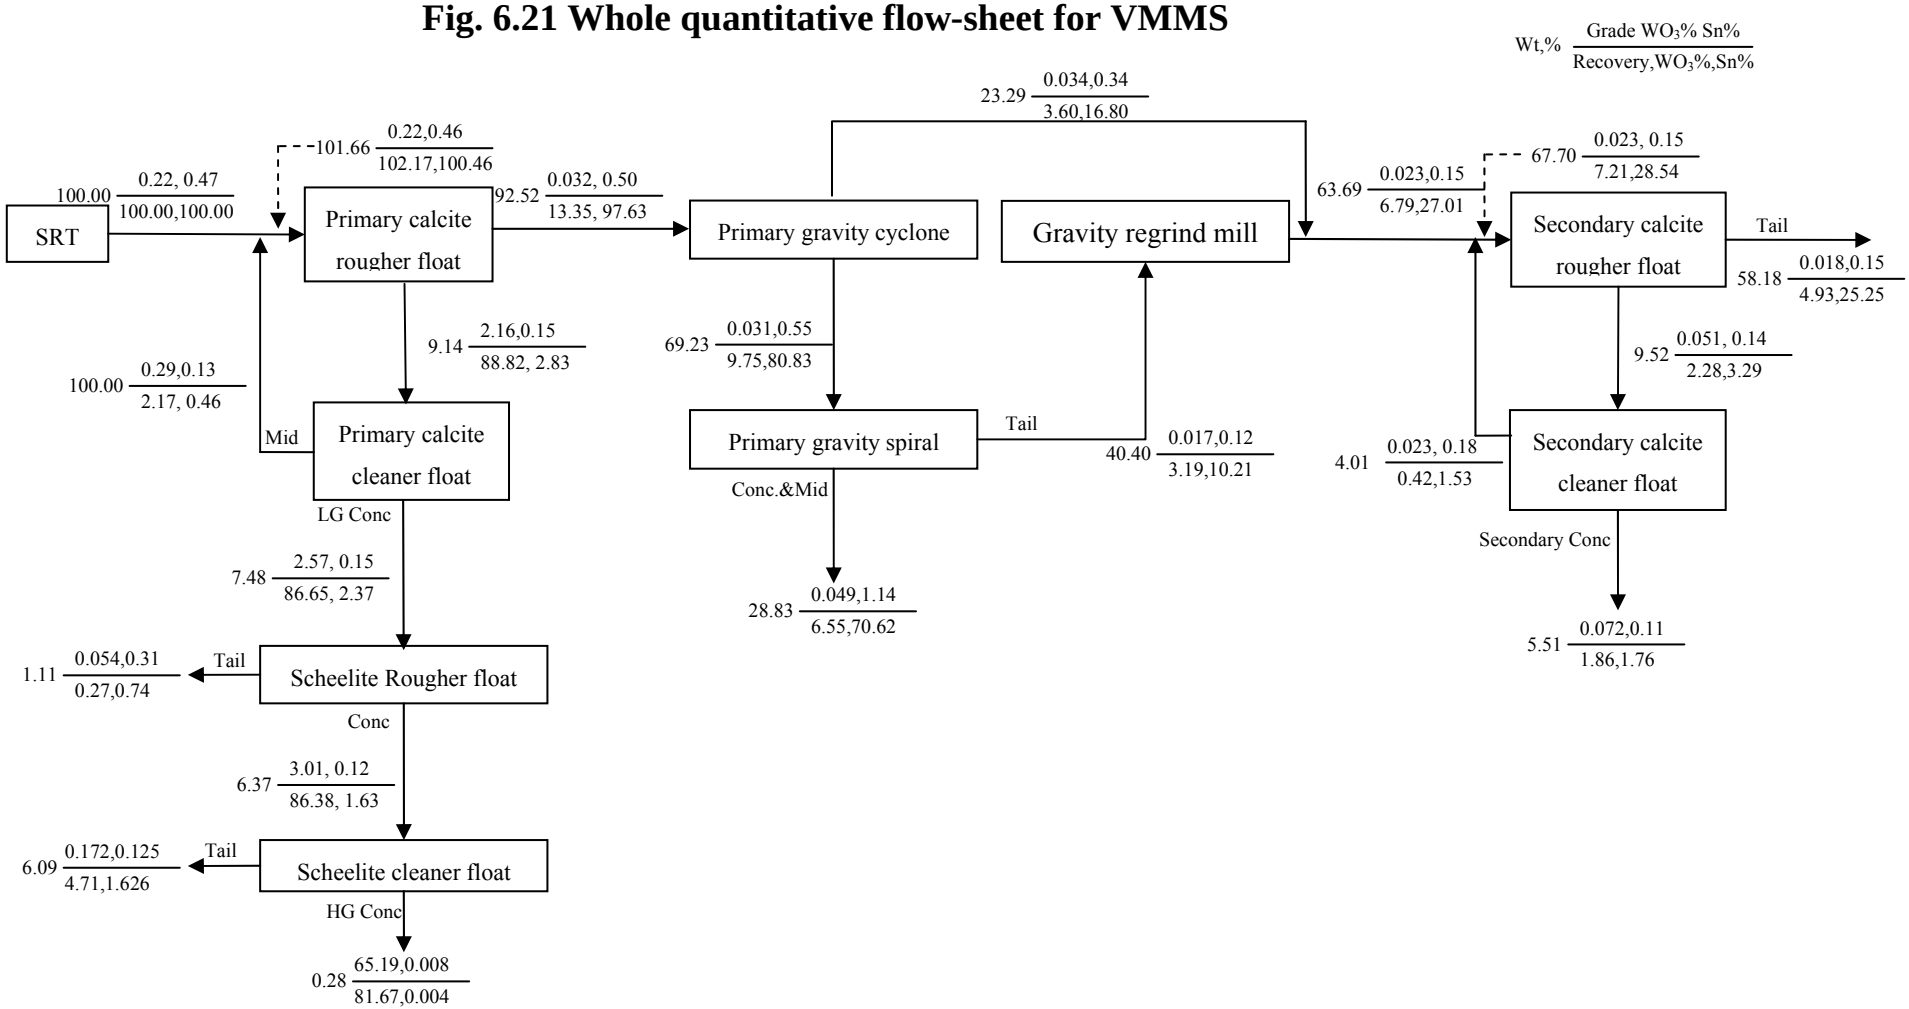


Fig 6.20 Flow-sheet of reagent rigime for VMMS

Fig. 6.21 Whole quantitative flow-sheet for VMMS

7. Mineral Processing test for 2# Skarn Ore (VM2S)

7.1 Primary calcite rougher and cleaner flotation

The major task of primary calcite rougher and cleaner flotation is to float out most of scheelite and calcite as well as fluorite and meanwhile to remain majority of tin minerals in tailings, to create favorable condition for tin recovery.

7.1.1 Tests on collector types for primary calcite rougher flotation

The comparison test on GYWA and GYW is conducted by the flow-sheet Shown in Fig.7.1 with the reagent regime and test result in Table 7-1 and Table 7-2, respectively. It is indicated that the performance of GYWA is a little better than that from GYW.

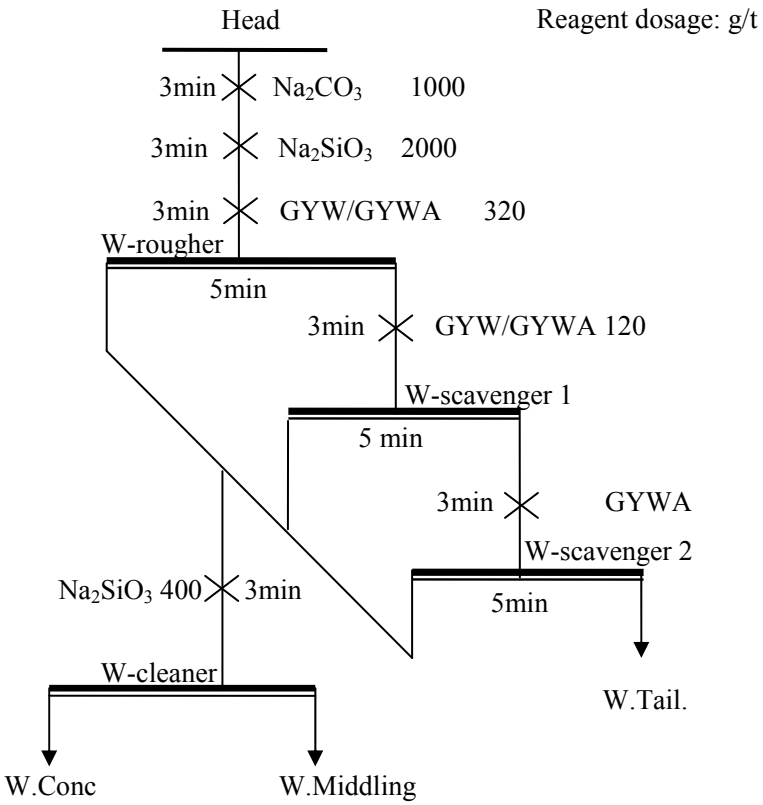

Fig7.1 Test flow-sheet of reagent for primary calcite rougher flotation VM2S

7.1.3 Dosage tests of sodium silicate and collector for primary calcite rougher

As the dosage of Na_2SiO_3 and GYWA will affect each other, so the dosage tests of Na_2SiO_3 and GYWA for primary calcite rougher are conducted by the flow-sheet in Fig.7-3 with its reagent regime and test result in Table 7-5 and Table 7-6. It is indicated that good results can be achieved when Na_2SiO_3 2000g/t and GYWA 320+160+80 g/t are used.

7.1.6 The locked cycle test for primary calcite rougher flotation

The locked cycle test for primary calcite rougher is conducted on the basis of open circuit test by the flow-sheet in Fig.7-6 and with its result in Table 7-10. It is indicated that the test result is quite good，the scheelite recovery is high with majority of tin minerals remains in tails. The tails is sent for process mineralogy study with its mineralogical result in Appendix 2 **(M2).**

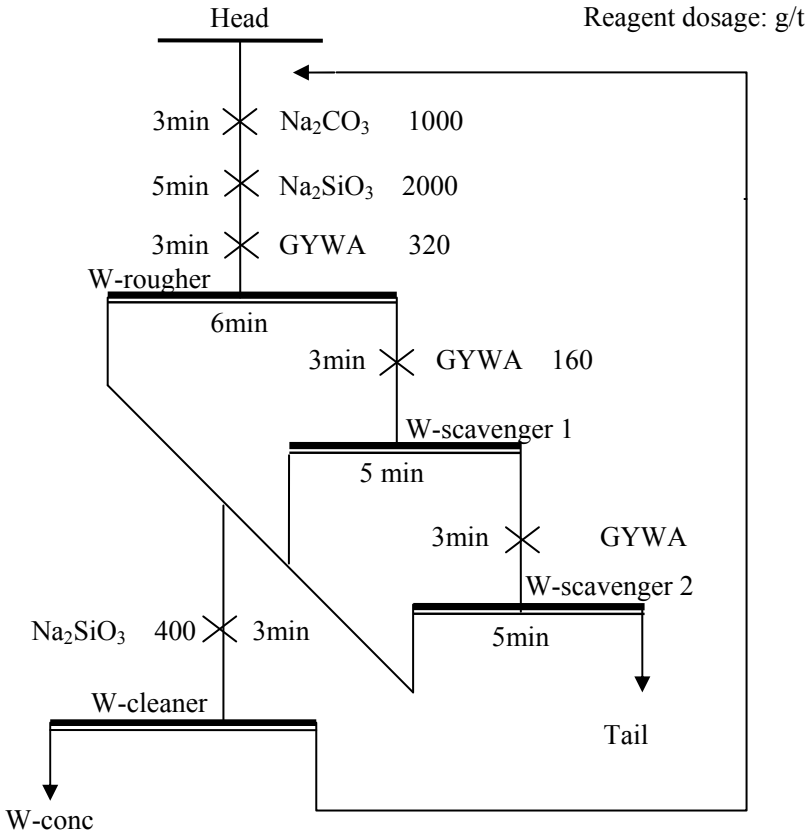

Fig7.6 Locked cycle test flow-sheet for primary calcite rougher flotation

Table 7.10 Locked cycle test result for primary calcite rougher flotation

7.2 Scheelite rougher flotation

Taking the W-concentrate got from primary calcite rougher and cleaner as the feed in order to reject the calcite and fluorite as much as possible and to upgrade the feed prior to the subsequent scheelite cleaner flotation. The test flow-sheet for scheelite rougher flotation is shown in Fig.7.7 and the result in Table 7-11

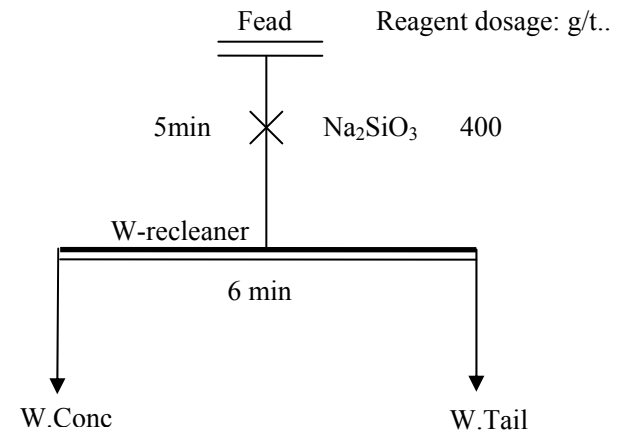

Fig. 7.7 Flow-sheet of scheelite rougher flotation cleaner

Table 7-11 Test result of scheelite rougher flotation

Product	Wt.%		Assay,%		Recovery,WO_3%		Recovery,Sn%	
	Stage	Rom	WO_3	Sn	Stage	Rom	Stage	Rom
W.Conc	89.64	7.97	5.96	0.14	99.29	93.08	90.31	3.46
W.Tail	10.36	0.92	0.369	0.13	0.71	0.67	9.69	0.37
Feed	100	8.89	5.38	0.14	100.00	93.75	100.00	3.83

It is shown that after scheelite rougher flotation, many calcite are rejected, the feed for scheelite cleaner flotation is upgraded.

7.3 Scheelite cleaner flotation

Taking the W-Conc. got from Fig.7.7 as the feed for scheelite cleaner flotation, following batch tests are conducted to determine suitable parameters for scheelite cleaner flotation. Feed pulp density is normally R 65%

7.3.1 Test on Na_2SiO_3 dosage for Conc. from rougher flotation

Test on Na_2SiO_3 dosage for W.Conc. from rougher flotation is conducted by the flow-sheet shown in Fig.7.8 with the test result in Table 7-12. It is indicated that the better result can be achieved when sodium silicate dosage is 60000 g/t.feed.

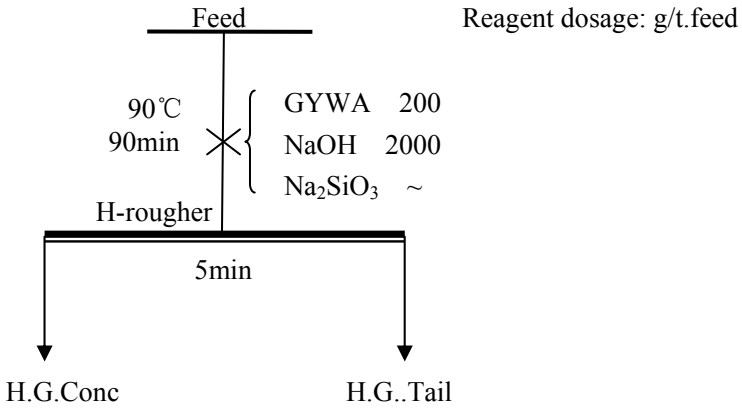

Fig 7.8. Flow-sheet of heated flotation for VM2S

7.3.2 Test on NaOH dosage for Conc. from rougher flotation

In our improved “Petrov Method”, the NaOH is used to intensify the depression on gangue minerals, especially on calcium-bearing gangue minerals. Test on NaOH dosage for Conc. from rougher flotation is conducted by the flow-sheet shown in Fig.7.9 with the test result in Table

7-13. It is indicated that the better result can be achieved when sodium hydroxide dosage is 2000 g/t.feed.

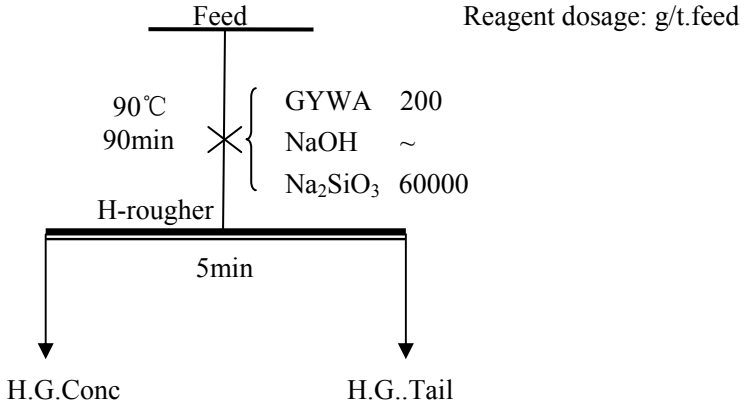

Fig 7.9. Flow-sheet of heated flotation for VM2S

7.3.3 Test on GYWA dosage for Conc. from rougher flotation

The Test on GYWA dosage for heated flotation is conducted by the flow-sheet shown in Fig.7.10 with the test results in Table 7-14. It is

indicated that better results can be achieved when total GYWA dosage is 500 (200+200+100) g/t.feed.

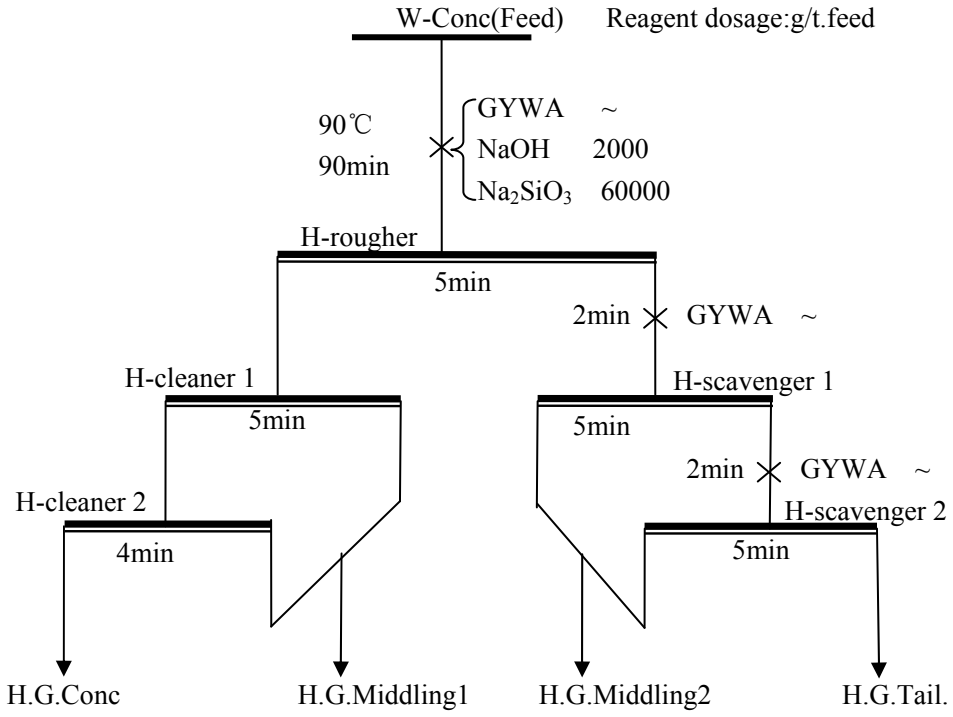

Fig 7.10 Flow-sheet of heated flotation for VM2S

7.3.5 The locked cycle test of heated flotation for mixed VMMS&VM2S sample

According to the requirement from Venture Minerals, we combine all the W-Conc. got from Fig. 6.9 (VMMS) and all the W-Conc. got from Fig.7.7 (VM2S) as the mixed feed for scheelite cleaner flotation. The locked cycle test is conducted with its flow-sheet presented in Fig.7-13 and the corresponding result presented in Table 7-16. Table 7.17 is the chemical analysis for the H.G. Concentrate got from Fig, 7-13. The H.G.

Concentrate obtained from Fig. 7-13 is sent for process mineralogy study with its result in appendix 1 **(M6).**

7.4 Primary gravity cyclone (classifier)(d50～26μm)

As the samples provided are limited, it is not enough for normal operation by hydro cyclone, after trial comparison on hydro cyclone and classifier, hydraulic classification is selected. The test on classifier is conducted by the flow-sheet shown in Fig.7.15 with the test results in Table 7-18. The table 7-19 and Table 7-20 are screen (size) analysis for the products got from classifier .It is indicated that the results are basically satisfactory.

7.5 Primary gravity spiral

Test of Spiral chute on sand from hydraulic classification is conducted.

The test flow-sheet is shown in Fig. 7.16 with corresponding test result in Table 7-21.The products of Conc. 1 and Conc.2 as well as Mid 1.2 is collected separately to be sent to Australia for further coarse tin recovery. Table 7-22 is the related data for products of Conc. 1 and Conc.2 as well as Mid 1.2. The combined sample of Conc. 1、Conc.2 and Mid 1.2 is sent for process mineralogy study with its result in appendix 2 **(M5)**.

7.6 Gravity regrind mill

According to the requirement, the products of Tail1+Mid2,2+Tail 2 from flow-sheet 7-16 will be reground to P_{80} -0.040mm and will be combined together with the overflow from hydraulic classifier to be the feed for further secondary calcite rougher flotation

7.7 Secondary calcite rougher flotation

The feed as shown in Table 7-23 for secondary calcite rougher flotation comprises Tail1+Mid2.2+Tail2 from flow-sheet 7-16 (reground to P80 -0.040mm) and the overflow from hydraulic classifier in Fig. 7.15.

The Screen analysis of feed sample for secondary calcite rougher

flotation is presented in Table 7-24.It is indicated that for VM2S sample, in the combined feed for secondary calcite rougher flotation, the tungsten and tin minerals are mostly distributed in -0.030mm fraction. Also, the chemical analysis of major elements of feed is shown in Table 7-25.

It is indicated that for VM2S sample, when only regulator of sodium silicate is added, the tin recovery in tailings is higher and meanwhile the calcite content in concentrate is also higher. So, only sodium silicate is recommended to be added in the locked cycle test.

In secondary calcite cleaner flotation, only a small amount of sodium silicate is added. The locked cycle test for secondary calcite (rougher $ cleaner) flotation

7.8 Locked cycle test for secondary calcite flotation

The locked cycle test flow-sheet for secondary calcite (rougher $ cleaner) flotation is shown in Fig. 7-18 with the corresponding test result presented in Table 7-28. It is indicated that through secondary calcite flotation, most of calcite minerals and part of fluoride are rejected, hence creating favorable condition for tin slime recovery. The two products from the test: secondary calcite flotation concentrate **(M4)** and secondary calcite flotation tail **(M3)** are sent for process mineralogy study with their results presented in appendix 2.

9. Conclusion

（1）Process Mineralogy study is conducted on two samples VMMS and VM2S provided by Venture Minerals Ltd. As the sulfide and magnetite in samples were already recovered in Australia using sulfide flotation and LIMS after sample's being ground to P_{80} -120 micron, only a small portion of sulfide and magnetite remains in samples. The major tungsten

mineral is scheelite with a very small amount of wolframite; tin minerals are mainly cassiterite with trace of stannite and stokesite; sulfide minerals are of great varieties including pyrrhotite, pyrite, a trace of chalcopyrite, chalcocite, arsenopyrite, etc.; iron oxide minerals are magnetite and siderite, while other oxide minerals include vonsenite, ilmentite, limonite, rutile, etc.; gangue minerals are dominated by biotite and amphibole, followed by vesuvianite, pyroxene, andradite, calcite, quartz, feldspar, chlorite, etc.. The size distribution of valuable is uneven, mostly ranging between 0.01mm-0.08mm, the liberation degree for tungsten minerals is about 89% while for tin minerals is lower, only about 62%.

（2）The principal flow-sheet adopted is: scheelite-calcite bulk flotation followed by their separation in heating process---preparation for tin recovery by de-sliming and spiral separation as well as pre-calcite rejection for further coarse tin gravity separation and slime tin flotation in Australia.

（3）Scheelite-calcite bulk flotation is conducted using sodium carbonate and sodium silicate as regulators, GYWA as collector, after calcite--rejecting by calcite cleaner, good scheelite rough concentrate with high recovery can be achieved, while most of tin minerals remain in the tailings of scheelite-calcite bulk flotation, creating favorable condition for further tin recovery.

（4）In heating process, the improved “Petrov method” is adopted, the

qualified scheelite concentrate is obtained with high recovery. The related parameters for heated flotation are studied and compared in detail. Quire good test results are achieved.

（5）As the overflow of hydraulic classifiers and the tail from reground spiral tails still contains a certain amount of fine calcite, the secondary calcite rougher and cleaner flotation is adopted, hence benefiting tin slime flotation.

（6）It is confirmed that pre-magnetic separation is not suitable for the two kinds of ores (VMMS and VM2S) due to serious loss of tungsten and tin minerals in Mags.

（7）For VMMS sample, when head is assaying 0.22% WO_3 and 0.47% Sn, the scheelite concentrate assaying 65.17% WO_3 with recovery 81.67% WO_3 can be obtained, about 95.87% of tin is sent for further tin recovery. As fro VM2S sample, when head is assaying 0.51% WO_3 and 0.25% Sn, the scheelite concentrate assaying 67.7617% WO_3 with recovery 88.43% WO_3 can be obtained, about 95.63% of tin is sent for further tin recovery. The above results are satisfactory.

Acknowledgement

The test team would like to express the sincere thanks to GZRINM and Venture Minerals Ltd for their support in whole process of tests. Also sincere thanks to Mr. Geoff Beros for many times of valuable technical discussion and great assistance

Appendix 1

The mineralogical inspection for VMMS is shown in Table 1, and the corresponding photos are shown after the notes. Table 2 is size distribution of main minerals in products.

1. GENERAL

1.1 BACKGROUND

Venture Minerals are working on the development of their Mt. Lindsay tungsten / tin / iron ore project in Tasmania. Recent communications with Venture Minerals personnel – Geoff Beros (General Manager – Metallurgy) and Jason Amaranti (Senior Metallurgist) have defined the currently proposed process flowsheet for the Mt Lindsay project as per the flowchart below.

Upfront gravity separation was considered as an option, but eliminated from the proposed flowsheet in favour of grinding all feed material to P_{80} 125µm to liberate most of the iron and sulphide minerals and allow their recovery/removal via magnetic separation and sulphide flotation.

Consideration was also given to incorporating a stage of high intensity magnetic separation to remove paramagnetic minerals identified in the ore, but this option was subsequently eliminated from the proposed flowsheet due to uncertainty about the amount of this material across the ore.

The aim of the proposed test work by Mineral Technologies will be to better define the gravity separation stages in the flowsheet above, processing deslimed, non-magnetic, sulphide and "coarse" primary calcite flotation sinks material, and determining what tin grade can be achieved in the gravity concentrate.

The above flowsheet is dynamic. Further upgrading of the gravity concentrate is likely to include sulphide flotation (to remove pyrites) while the gravity tailings will require regrinding to P_{80} 40µm before a "Fine" Secondary Calcite Flotation stage is developed

and before the coarse and fine calcite flotation concentrates can be brought together for scheelite flotation.

Further information was provided on the estimated mass deportments on the basis of testwork completed to date and this data indicates that ~65–70% of the tonnage fed to the process plant will report to the primary gravity cyclones. So, for a proposed 1.3 Mt/a plant, this will equate to ~0.9 Mt/a or ~110 t/h (for 8,000 annual operating hours) going to the primary gravity cyclones.

1.2 MATERIAL

Three samples were delivered to CPG Mineral Technologies' Metallurgical Services test facility on 24 April 2012. The samples were FM1 rougher stage spiral feed, concentrate and middling produced in flowsheet testwork conducted by Amdel in Western Australia.

1.3 TERMS OF REFERENCE /SCOPE OF WORK

The scope of work was defined in testwork proposal MT MS 11074 rev 3.0, issued 11 May 2012. The scope of work is appended. The optional scope of work items (F and G) were not taken up by the client.

Approval and acceptance of the proposal was received from Geoff Beros on 21 May 2012.

A purchase order (#170) was received from Venture Minerals on 22 May 2012.

1.4 SUMMARY

Three samples of blended Mt Lindsay ore were received from Amdel (Perth) for gravity circuit testwork. The samples were prepared spiral feed, spiral concentrate and spiral middling. The feed sample was characterised in terms of assay by size analysis and spiral release testwork was conducted on an FM1 model spiral separator to compare the performance with the results achieved by Amdel using the same spiral model. The spiral concentrate and middling samples (produced by Amdel) were each subjected to additional FM1 spiral release testwork to constitute cleaner and scavenger stages. Reserve sample from the spiral testwork was processed over stages of wet table separation to evaluate performance and determine the potential for producing high grade tin concentrate.

Rougher Spiral Feed

The feed sample contained 0.44% total Sn and 0.09% WO_3 as the valuable components. The sample also contained 0.15% As, 0.54% S and 19.7% Fe. Soluble Sn comprised approximately 10% of the total Sn value. B and F levels were determined to be 0.14% and 0.62% respectively.

The sample had been milled to an advised target P_{80} of 125µm and deslimed. The particle size range of the sample was ideal for FM1 spiral with a D_{50} in the order of 90µm and minimal mass below 20µm. 80% of the Sn and 90% of the WO_3 were coarser than 45µm.

Rougher spiral release testwork confirmed good upgrading of Sn and WO_3 with grades of approximately 5% Sn and 1% WO_3 achieved in a low mass yield of 6% at recoveries of 60% and 70% respectively. Testing at two different feed rates indicated that higher feed rates of up to 1.5t/h could be used with only a small decrease in performance compared with a standard feed rate of 1.0t/h. Feed slurry density was maintained at approximately 35% solids.

Rougher Spiral Middling

The received sample contained 0.2% total Sn and 0.013% WO_3. The sample also contained 0.13% As, 0.4% S and 19% Fe. Soluble Sn comprised approximately 10% of the total Sn value. Soluble Sn, B and F levels were determined to be 0.05%, 0.13% and 0.46% respectively.

Spiral release testwork indicated the feed contained residual gravity recoverable Sn and WO_3 with grades of approximately 0.9% Sn and 0.05% WO_3 achieved in a low mass yield of 5% at recoveries of approximately 20% for both Sn and WO_3. A single feed rate of 1.0t/h at 35% solids density was tested but based on the rougher stage results it is expected that a higher feed rate could be used with minimal decrease in performance.

Rougher Spiral Concentrate

The received sample contained 1.6% total Sn and 0.27% WO_3. The sample also contained 0.5% As, 1.2% S and 23% Fe. Soluble Sn comprised approximately 10% of the total Sn value. Soluble Sn, B and F levels were determined to be 0.06%, 0.25% and 0.48% respectively.

Spiral release testwork indicated good upgrades of Sn and WO_3 with grades of approximately 8% Sn and 1.5% WO_3 achievable in a mass yield of 12% at recoveries of 70% and 80% respectively. A single feed rate of 0.9t/h at 24% solids density was tested but based on the rougher stage results it is expected that a higher feed rate could be used with minimal decrease in performance. The low feed density was due to the small mass of feed available. The typical feed density would be 30 to 35% solids.

Reconstituted sample from the spiral release testwork was processed over a two stage wet table circuit with the second (cleaner) stage treating concentrate from the first (rougher) stage. From the second stage a concentrate was produced at a table circuit mass yield of 0.9% that contained 52.9% total Sn and 9.8% WO_3. The concentrate also contained relatively high levels of As (5.9%) and S (1.3%). Recoveries of Sn and WO_3 in the wet table circuit were 29% and 32% respectively. The relatively low recoveries were due to the requirement for producing a Sn concentrate of the highest possible grade. A concentrate of lower grade containing 18% total Sn, 3% WO_3, 5.7% As and 3.4% S could be produced (in a table circuit mass yield of 7.5%) at recoveries of 80% (Sn) and 86% (WO_3) respectively and should be suitable for feed to a flotation circuit to remove sulphides (As and S).

Based on results provided by Amdel for the rougher stage bulk spiral processing which produced the concentrate for table testwork conducted by MT, the overall recovery of Sn and WO_3 was 15% and 22% respectively (calculated back to prepared rougher spiral feed) to produce a high grade Sn concentrate at an overall mass yield of 0.10%. The lower grade concentrate (18% Sn) achieved recoveries of 42% (Sn) and 57% (WO_3) at an overall mass yield of 0.85%.

1.5 CONCLUSIONS AND RECOMMENDATIONS

1. The testwork indicated the received samples were ideally suited to gravity upgrading using the FM1 spiral separator and wet tables based on the particle size and liberation characteristics.

2. Due to the small sample mass available for testwork the wet table processing was carried out using a laboratory-scale unit. In order to more accurately predict plant performance, a larger sample should be processed that would allow a Holman 2000 (one quarter production scale) to be used. In addition, a larger sample should be of sufficient mass to be processed sequentially through a full gravity circuit (two spiral stages and two to three wet table stages) to provide accurate measurement and confirmation of the gravity circuit performance.

3. It is recommended that consideration be given to the production of a lower grade crude Sn concentrate from the wet table circuit for subsequent stages of flotation to remove high density sulphide and tungsten minerals. A relatively low recovery of Sn and WO_3 was achieved experienced in the final stage in order to produce a Sn concentrate containing >50%Sn.

The conclusions and recommendations contained within this report pertain to the samples as received, and any variations in feed type or specification, unless specifically addressed are beyond the scope of this report.

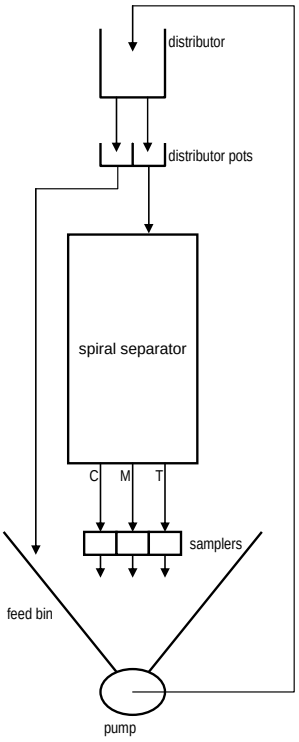
2. TESTWORK PROCEDURE

2.1 WET SEPARATION TESTWORK



2.1.1 Spiral Testwork

Closed Circuit Operation

Spiral testwork was conducted in a closed circuit test rig consisting of the production scale spiral separator (single start), a sump, pump and full-stream deflection samplers. The pump discharge reported to a distributor with a portion of the feed stream directed to the spiral feed box and the remainder returning to the feed sump.

The spiral feed stream flows down the spiral trough with the high-density material migrating toward the centre column and the low density material being transported to the outer trough. Concentrate splitters recover the high density material to a concentrate channel, whilst intermediate density and low-density streams are directed by further splitters into individual product collection channels within the product collection box. Each stream then returns to the sump via timed, full-stream deflection samplers.

The test rig was started up with water and solids added to the sump until the required test parameters were established. For testing of fine feeds, the homogeneous feed was held at the desired pulp density as slurry in an external tank and was transferred to the spiral feed sump as required. The samplers were then operated and the products collected separately.

closed circuit spiral test rig

The products were weighed wet and then dried. The resultant data were then processed and used to calculate the physical parameters (rate (t/h) and %solids) of each stream and the feed. Sub-samples of each stream were then representatively extracted using riffle or carousel splitters for assay purposes.

2.1.2 Wet Table

Wet shaking tables employed for the duty were *Holman 2000* (one-quarter of full size) and laboratory-scale *Wilfley* models. Dry or dewatered feed was introduced at a constant rate into the feed box and dilution water was added. The products were collected into buckets with the aid of manually positioned splitters. Products were then dewatered and dried. The dried products were weighed and a sub-sample representatively extracted from each using a riffle splitter for assay purposes. The *Wilfley* laboratory-scale table was used as an analytical tool and not used for process design testwork. Process design testwork would be based on scaled up data from *Holman* table testwork.

Bulk wet table processing was conducted using a circuit comprising feed sump and pump with pump discharge reporting to a distributor with a portion of the feed stream reporting to the wet table feed box and the remains returning to the feed sump. New feed was added to the feed sump at an equivalent rate in order to maintain constant operating conditions.

2.2 SAMPLING AND ANALYSIS

2.2.1 Dry Sampling

Dry samples were sub-sampled using a 10-way rotary sampler fed by hopper and vibrating feeder or by a two-way riffle splitter.

2.2.2 Wet Sampling

Sub-samples of slurries were extracted by collecting aliquots of the homogenised slurry. Filter cakes were sub-sampled by extracting a division of the filter cake disc.

2.2.3 Size Analysis

Particle size analysis was carried out using 200mm diameter, certified square-mesh test sieves above 38µm aperture.

2.2.4 Cyclosizer Analysis

The Warman Cyclosizer is a laboratory precision apparatus for the rapid and accurate determination of particle size distribution within the sub sieve range. Each machine is calibrated individually before it leaves the works and typically separates at around 40, 30, 20, 15 and 11 microns. The Cyclosizer was developed for the mining industry, and a feature of the Cyclosizer separation is that it returns the size fraction for assay of microscopic examination so that information on liberation sizes can be gathered. The operation of the Cyclosizer is robust so that although some operator skill is required, it is less sensitive than some other competing processes that do not produce size fractions for examination.

Particles are separated according to their Stokes equivalent diameter and in this sense differ from say mesh screen sizes, which rely on whether or not a grain will pass a square aperture. Thus, when plotting the sizing results, there is often a small inflection in the graph associated with the change in sizing principle. When Cyclosizer sizing data are plotted against sizing data using other techniques, there is generally a small parallel shift for each technique that is a function of how the technique defines particle size.

Because the Cyclosizer uses the Stokes equivalent diameter, the fractions produced are specific gravity dependant. It is convention to express the sizings as quartz equivalents, but in reality, these sizings need to be corrected for variations in specific gravity. Corrections are calculated as part of the standard operating technique. Although a sizing may use an average specific gravity it is possible for discrete minerals to be classified separately. For instance in the first cyclone that separates at say 40 micron quartz equivalent this will also capture a 14 micron gold grain. Thus heavier minerals report to higher cyclones in the configuration.

2.2.5 XRF Analysis

XRF and ICP chemical analyses were carried out by Ultra Trace Laboratories (Perth, Western Australia). The samples for analysis were pulverised in a tungsten carbide ring mill.

For XRF analysis a sub-sample of the pulverised pulp was cast using a 12:22 flux with the addition of sodium nitrate to form a glass bead. The bead was then analysed using X-ray fluorescence spectrometry (XRF) for standard mineral suite analytes.

For ICP analysis a sub-sample of the pulverised pulp was fused with sodium peroxide and subsequently the melt has been dissolved in dilute Hydrochloric acid for analysis. Because of the high furnace temperatures, volatile elements are lost. Mo, Sn, W have been determined by Inductively Coupled Plasma (ICP) Mass Spectrometry.

Reserve sample pulps from Ultra Trace were then sent to SGS (Townsville, Queensland) for analysis for soluble Sn, B and F. The sample were also analysed by ICP method for Sn and WO_3 suite elements for comparison to Ultra Trace results.

2.3 CALCULATIONS AND DEFINITIONS

2.3.1 Mass Balances

Mass balances were conducted for single stage separations using mass of the process streams where possible. In certain circumstances a specific stream mass may be calculated by difference from the feed mass.

Circuit balances were calculated from final end streams and may therefore vary slightly from the individual separation stage balances.

2.3.2 Accuracy and Precision of Measurements

It should be noted that although best practice and care is used for all test work, the data presented is subjected to experimental and analytical errors and hence all data has inherent inaccuracy.

The number of decimal places quoted in this report is used for calculation purposes and clarity only and does not infer any level of accuracy.

2.3.3 **Normalising**

In order to compare the separation performance of different units or interrogate the optimum feed operating conditions to single units, it is often required to normalise the feed grade for that particular stage. The procedure utilised in this report for normalising the data is as follows:

Adjustment to cumulative weight take

The most soundly based adjustment to the weight take, is to modify the cumulative weight take to successive products in the proportion to the alteration in the feed grade.

This is satisfactory for weight takes less than the feed assay, however, at weight takes in excess of this limit, the adjustment must be made in proportion to the complement of the feed assay (i.e. to the quantity 1 – *f*, where *f* is the feed assay) otherwise predicted weight takes in excess of 100% can be generated.

General formula is:

(1) NWt = IF (Wt < Fd, Wt x NFd/100, NFd + (Wt - Fd) x (1 – NFd/100) / (1- Fd/100))

Where:

- NWt is the normalised weight take
- Wt is the original weight take
- Fd is the original feed grade
- NFd is the normalised feed grade (target content)

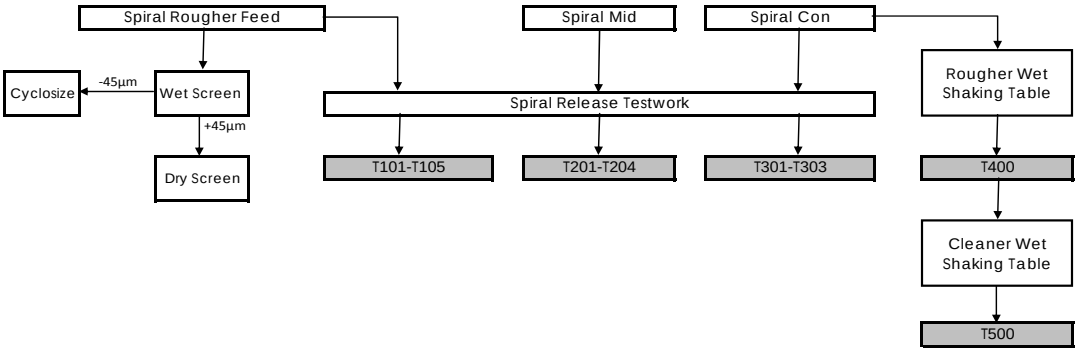
Adjustment to assay data

The assay data must also be corrected; however, simply assigning the same upgrade ratio can produce assays in excess of 100%. Either recovery (distribution) or separation efficiency parameters could be held constant. There are arguments for and against each alternative; however, it has been found that utilising constant separation efficiency is the most effective.

2.3.4 Glossary of Terms and Abbreviations

The following list depicts abbreviations and acronyms of technical terms that may be used throughout the report.

TERM	DESCRIPTION
HM	heavy mineral with specific gravity >2.85 sg
LM	light mineral with specific gravity <2.85 sg
VHM	very heavy mineral of +4.05 sg, which includes zircon, monazite, TiO_2 minerals such as primary ilmenite & rutile
LHM	light heavy minerals in the +2.85 to –4.05 sg range, which may include TiO_2 minerals such as altered ilmenite, leucoxene and pseudo-rutile May be further sub-divided (commonly at 3.6 sg) for more specific profiling of TiO_2 minerals.
HMC	heavy mineral concentrate (generally wet plant final product)
O/F	overflow
U/F	underflow
>	greater than
<	less than
HLS	heavy liquid separation
Spiral	spiral separator
s.g / SG	specific gravity
conc.	concentrate
mid	middling
tail	tailing
slime tail	generally refers to the overflow fraction of a bulk tailing that has been classified or dewatered
sand tail	generally refers to the underflow fraction of a bulk tailing that has been classified or dewatered
core	sub-sample taken from a drum of sample using an auger or other spearing device
wt % stage	mass distribution for an individual stage of separation or processing
wt % head	mass distribution calculated from the feed to a defined multi stage circuit
w/w	ratio or proportion based on two masses
cyclone	hydrocyclone
bleedout	processing of a bulk sample through an open circuit test rig
sighter test	small size timed samples of spiral products in a closed circuit test rig.
spiral release curves	mass yield versus mineral recovery, separation efficiency or grade for a specified analyte at a selected operating condition
KPI	Key Performance Indicator such as plant feed rate, HMC target grade, WGC recoveries,



3. RESULTS AND DISCUSSIONS

3.1 SAMPLE RECEIPT & PREPARATION

The spiral concentrate and middling were received as dewatered slurry. The spiral feed was received as dilute slurry. The slurry sample was dewatered and each sample was separately homogenised by cone and quarter method. Sub-samples were extracted for moisture determination, head assay and assay by size analysis (spiral feed sample only). The calculated dry weights of the received samples are listed below.
Rougher FM1 Spiral Feed (cyclone underflow) (received as slurry) – calc dry weight: 68.5kg
Rougher FM1 Spiral Concentrate – cal dry weight: 19.7kg
Rougher FM1 Spiral Middling – calc dry weight: 26.3kg

3.2 TESTWORK FLOW DIAGRAM

The flow diagram below depicts the actual testwork conducted.

3.3 ROUGHER SPIRAL TESTWORK

This testwork was carried out at the request of the client as verification of the performance data achieved from testwork conducted by Amdel on the same spiral model (FM1 – 6.5 turn version).

A series of five release tests were carried out. Three tests were conducted at feed loading of 1.0-1.1 t/h, 30-35% solids. Two further (un-scoped) release tests were conducted at a higher loading of 1.4-1.5 t/h, 30-35% solids. Splitters were adjusted between tests to vary the concentrate, middling and tailing mass yields. The test fractions were weighed wet, dried at low temperature (<70 degrees) and re-weighed. Sub-samples of each test fraction were extracted for assay. The mass flow and assay data were tabulated for each test and are presented in the appendices. Release curves for tin (Sn), tungsten (WO_3) and iron (Fe), arsenic (As), soluble tin (sol Sn), boron (B) and fluorine (F) were delineated from the test data. The release curves for recovery versus mass yield are presented below. For clarity Sn, WO_3, Fe and As curves are presented in separate charts from the soluble Sn, B and F. The release curves for grade and separation efficiency are presented in the appendices.

The release curves for recovery and grade comparing Amdel and MT testwork at 1.0 t/h are presented in the appendices. The Sn recovery and grade was significantly better for MT testwork while the WO_3 recovery was slightly better. However it is noted

that the calculated feed grades of both Sn and WO_3 were significantly lower for the Amdel testwork. The reason for this is not clear.

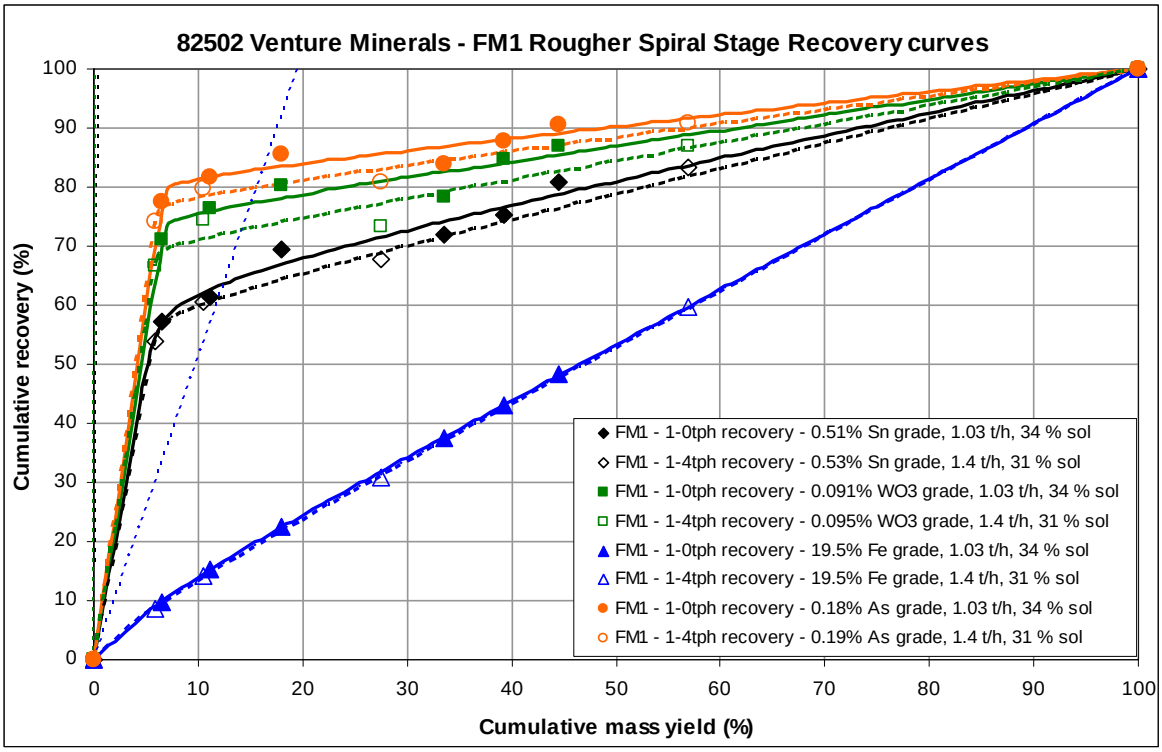


Figure 1: Rougher Spiral Recovery Curves for Sn, WO_3, Fe & As

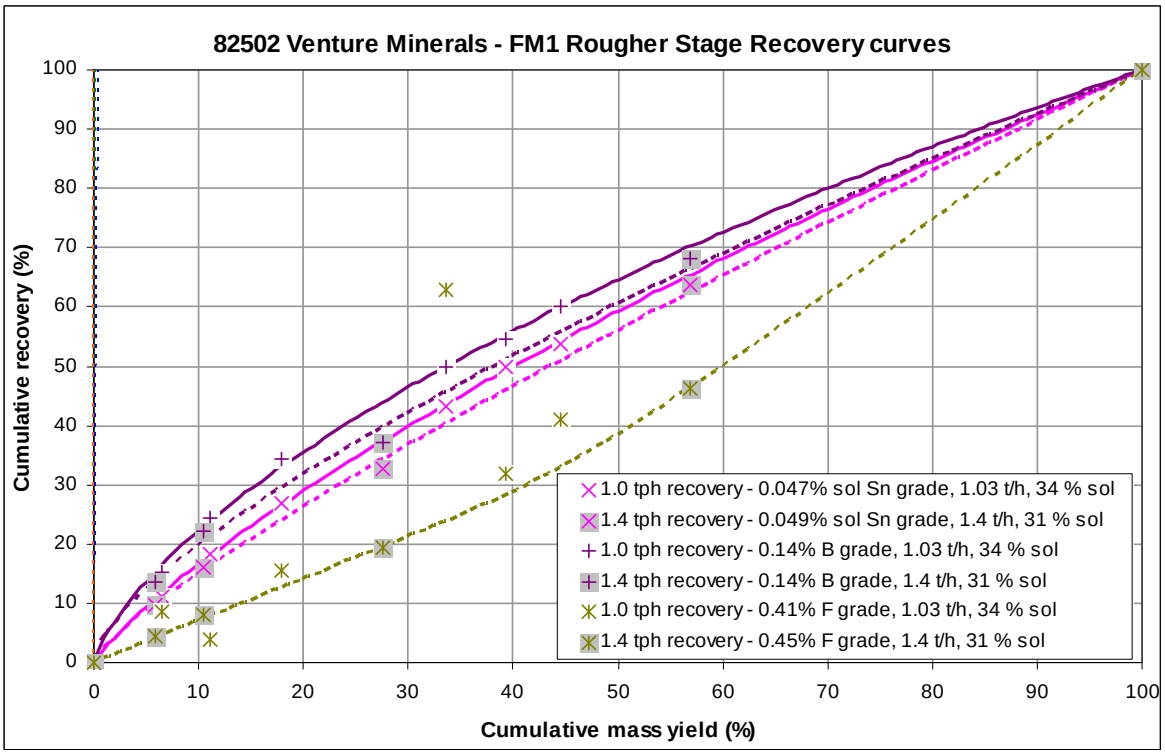

Figure 2: Rougher Spiral Recovery Curves for soluble Sn, B & F

The recovery curves in Figure 1 and Figure 2 show:

- Recoveries of approximately 60% Sn, 70% WO_3 and 75% As were achieved at the lowest mass yield collected in the testwork (6%). This indicates the recovery of well liberated and easily recoverable mineral.
- For mass yields >10% the gradient of the recovery curves significantly reduces, indicating poor separation and minimal upgrading of the remaining S, WO_3 and As. This typically indicates the remaining minerals are very fine, coarse or unliberated.
- The gradient of the recovery curve for iron (reported as Fe) was only slightly elevated above the line of no separation indicating minimal upgrading such that Fe recovery was only marginally higher than the mass yield.
- The recoveries for soluble Sn and B were only marginally higher than the mass yield indicating poor response to gravity upgrading. The F data points were very scattered and it was only possible to define a curve for the tests conducted at 1.4t/h. This curve shows that F mineral was preferentially recovered to tailing with the curve showing negative recovery.

The grade curves in the appendices show:

- The feed contained 0.5% Sn. A concentrate containing approximately 5% Sn was achieved at the lowest tested mass yield (6%). The feed grade for soluble Sn was 0.05%. At the lowest mass yield the concentrate contained approximately 0.08% soluble Sn.
- The feed contained between 0.09 and 0.10% WO_3. A concentrate grade of just over 1.0% WO_3 was achieved at the lowest tested mass yield (6%).
- The feed contained 19% Fe. At the lowest mass yield to concentrate, the Fe grade was 29%. The iron minerals were upgraded but to a much lesser extent than Sn, WO_3 or As.

Although the content of iron minerals in the feed is very high compared with the other minerals analysed they do not appear to significantly interfere with recovery of liberated Sn, WO_3 of As. The specific gravities cassiterite (Sn), scheelite (WO_3) and arsenopyrite (As) appear to be higher than most of the contained iron minerals. For both test series, the data points for these minerals in the mass yield range 25% to 35% are depressed and misaligned with other data points. This may be due to iron minerals competing with the other species in this region.

Some variation is apparent in the recovery curves for Sn, WO_3 and As from the test series carried out at different feed loadings. Notwithstanding analytical variation, it appears that recovery performance is slightly better at 1.0 t/h compared with the higher feed rate of 1.4t/h although the difference is marginal.

3.4 CLEANER SPIRAL TESTWORK

A series of tests were conducted using on an FM1 spiral at a feed loading of 0.9-1.0t/h, 24% solids using the supplied rougher concentrate as feed. As the mass of available feed was very low, it was not possible to increase the % solids above this level. A feed slurry density of 25% to 30% would be considered as typical for this ore type in a cleaner stage. The reduced density is unlikely to have a significant effect on performance.

Splitters were adjusted between tests to vary the concentrate, middling and tailing mass yields. The test fractions were weighed wet, dried at low temperature (<70 degrees) and re-weighed. Sub-samples of each test fraction were extracted for assay. The mass flow and assay data were tabulated for each test and are presented in the appendices. Release curves for tin (Sn), tungsten (WO_3) and iron (Fe), arsenic (As), soluble tin (sol Sn), boron (B) and fluorine (F) were delineated from the test data. The release curves for recovery versus mass yield are presented below. For clarity Sn, WO_3, Fe and As curves are presented in separate charts from the soluble Sn, B and F. The release curves for grade and separation efficiency are presented in the appendices.

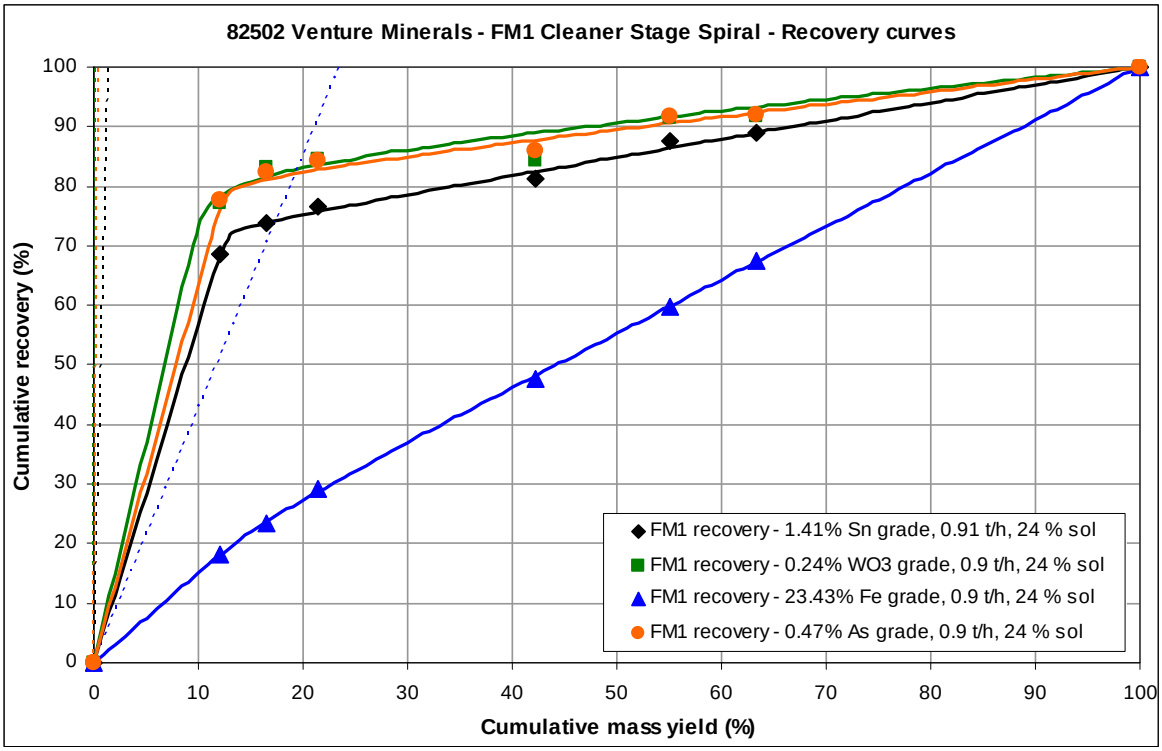

Figure 3: Cleaner Spiral Recovery Curves for Sn, WO_3, Fe & As

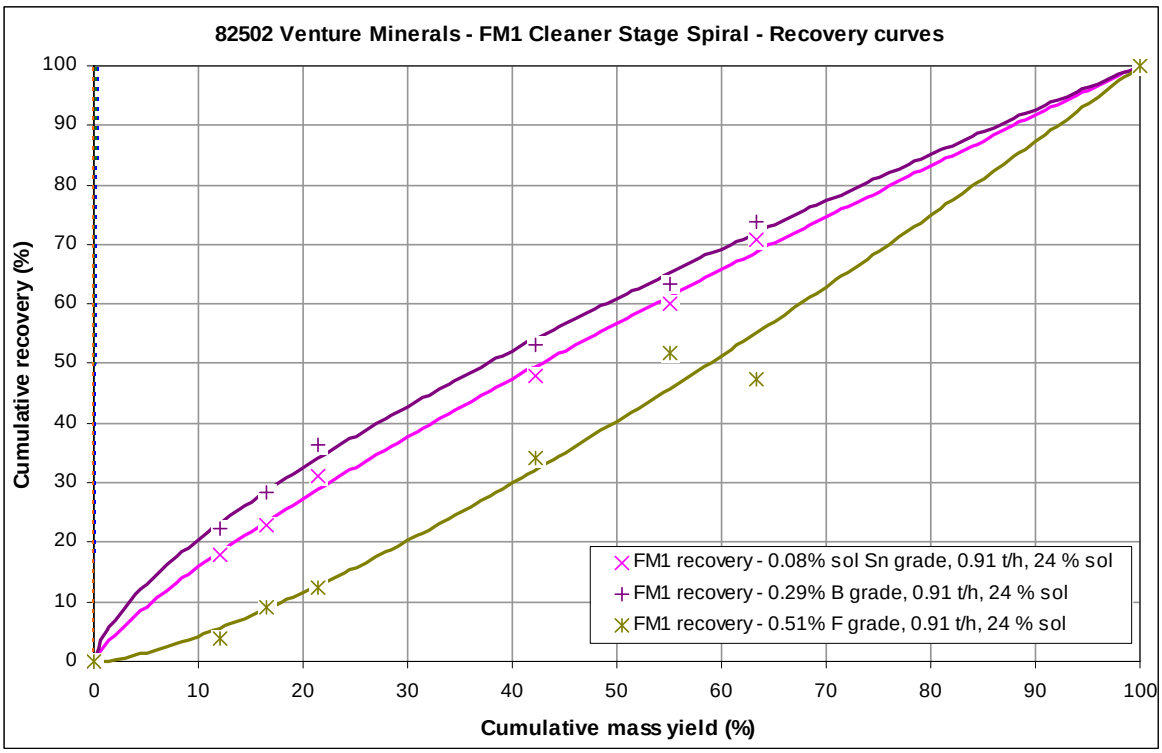

Figure 4: Cleaner Spiral Recovery Curves for soluble Sn, B & F

The recovery curves in
Figure 3 and Figure 4 show:

- Recoveries of approximately 68% Sn and 78% for both WO3 and As were achieved at the lowest mass yield collected in the testwork (12%). This indicates the recovery of well liberated and easily recoverable mineral. The recovery curves for WO3 and As are virtually identical.
- For mass yields greater than 10% to 15% the gradient of the recovery curves significantly reduces, indicating poor separation and minimal upgrading of the remaining S, WO3 and As. This typically indicates the remaining minerals are very fine, coarse or unliberated.
- The gradient of the recovery curve for iron (reported as Fe) was only slightly elevated above the line of no separation indicating minimal upgrading such that Fe recovery was only marginally higher than the mass yield.
- The recoveries for soluble Sn and B were only marginally higher than the mass yield indicating poor response to gravity upgrading. Despite some scatter in the F data points the curve showed that F mineral was preferentially recovered to tailing with the curve showing negative recovery.

The grade curves in the appendices show:

- The feed contained 1.4% Sn. A concentrate containing approximately 8% Sn was achieved at the lowest tested mass yield (12%). The feed grade for soluble Sn was approximately 0.08%. At the lowest mass yield the concentrate contained approximately 0.11% soluble Sn.
- The feed contained between 0.24% WO3. A concentrate grade of 1.5% WO3 was achieved at the lowest tested mass yield (12%).

- The feed contained 23% Fe. At the lowest mass yield to concentrate, the Fe grade was 35%. The iron minerals were upgraded but to a much lesser extent than Sn, WO_3 or As.

The inflection point for the recovery curves for both Sn, WO_3 and As occurred in the mass yield range 12% to 15%. This indicates that mineral recovered beyond this mass yield range is not readily amenable to spiral recovery and is likely to have been present in the feed due to the advised mass yield of 15% collected from the rougher stage, where the mass yield limit for readily recoverable mineral was 7 to 10%.

3.5 SCAVENGER SPIRAL TESTWORK

A series of tests were conducted using on an FM1 spiral at a feed loading of 1.0t/h, 30-35% solids using the supplied rougher middling as feed. Splitters were adjusted between tests to vary the concentrate, middling and tailing mass yields. The test fractions were weighed wet, dried at low temperature (<70 degrees) and re-weighed. Sub-samples of each test fraction were extracted for assay. The mass flow and assay data were tabulated for each test and are presented in the appendices. Release curves for tin (Sn), tungsten (WO_3) and iron (Fe), arsenic (As), soluble tin (sol Sn), boron (B) and fluorine (F) were delineated from the test data. The release curves for recovery versus mass yield are presented below. For clarity Sn, WO3, Fe and As curves are presented in separate charts from the soluble Sn, B and F. The release curves for grade and separation efficiency are presented in the appendices.

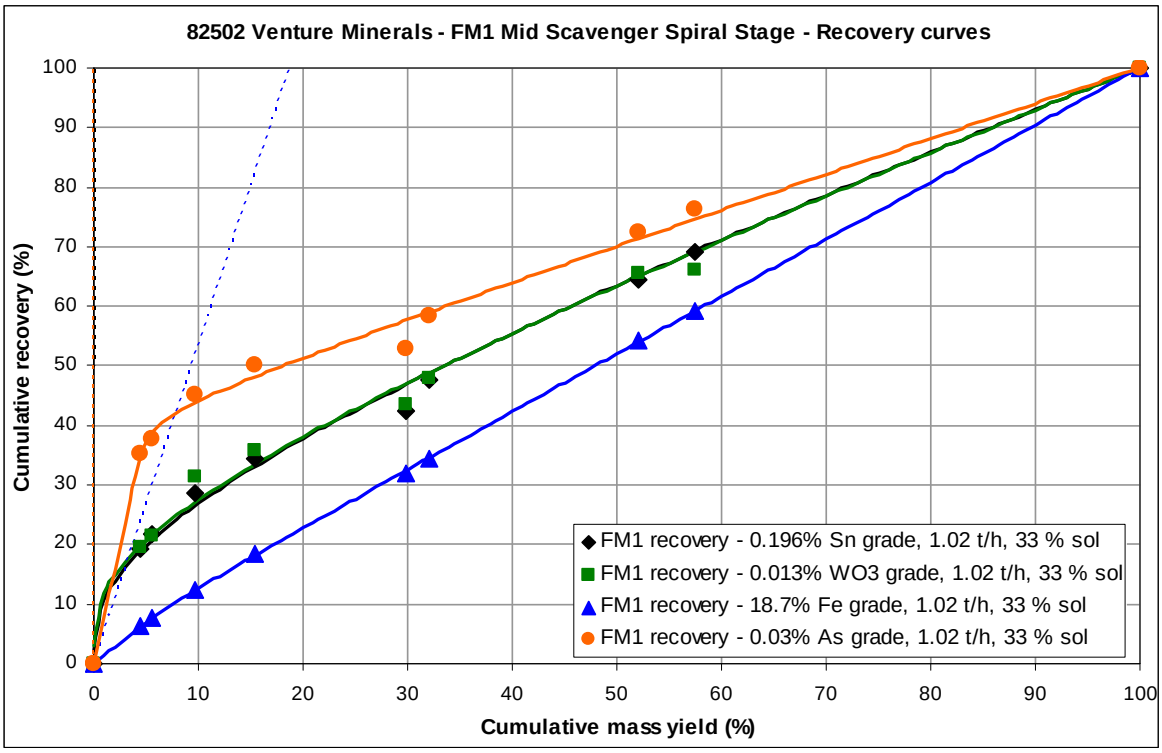

Figure 5: Scavenger Spiral Recovery Curves for Sn, WO3, Fe & As

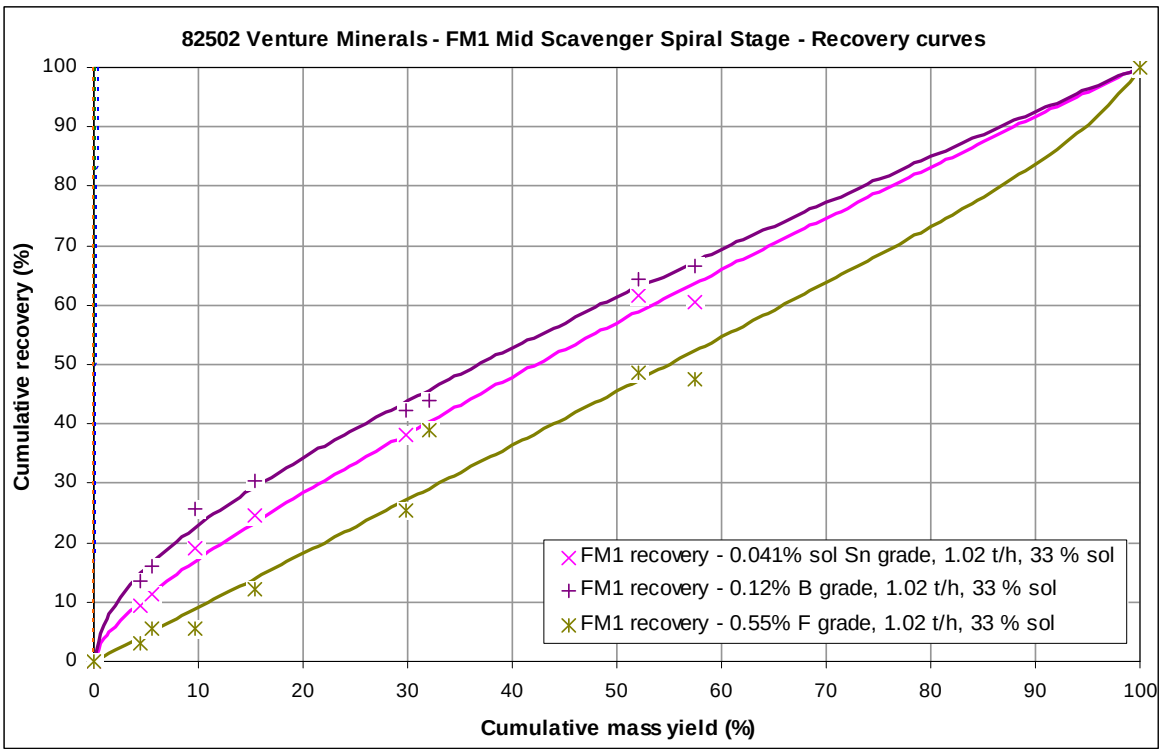

Figure 6: Scavenger Spiral Recovery Curves for soluble Sn, B & F

The recovery curves in Figure 5 and Figure 6 show:

- Recoveries of approximately 20% for both Sn and WO_3 and 35% for As were achieved at the lowest mass yield collected in the testwork (approximately 5%). This indicates a small quantity of recoverable mineral remaining in the rougher middling. The recovery curves for Sn and WO_3 are virtually identical.
- For mass yields greater than 10% the gradient of the recovery curves significantly reduces, indicating poor separation and minimal upgrading of the remaining Sn, WO_3 and As. In this stage, this probably indicates that the residual minerals are not sufficiently liberated for gravity recovery.
- The gradient of the recovery curve for iron (reported as Fe) was only slightly elevated above the line of no separation indicating minimal upgrading such that Fe recovery was only marginally higher than the mass yield.
- The recoveries for soluble Sn and B were only marginally higher than the mass yield indicating poor response to gravity upgrading. Despite some scatter in the F data points the curve showed that F mineral was preferentially recovered to tailing with the curve showing negative recovery.

The grade curves in the appendices show:

- The feed contained 0.2% Sn. A concentrate containing approximately 0.8% Sn was achieved at the lowest tested mass yield (5%). The feed grade for soluble Sn was approximately 0.04%. At the lowest mass yield the concentrate contained approximately 0.09% soluble Sn.
- The feed contained between 0.013% WO_3. A concentrate grade of 0.6% WO_3 was achieved at the lowest tested mass yield (5%).

- The feed contained 19% Fe. At the lowest mass yield to concentrate, the Fe grade was 26%. The iron minerals were upgraded but to a much lesser extent than Sn, WO_3 or As.

The inflection point for the recovery curves for both Sn, WO_3 and As is likely to occur at a very low mass yield (less than 5%) indicating a very small proportion of gravity recoverable minerals were contained. The results show that there was some residual W and Sn minerals in the rougher stage middling that had not been recovered to rougher concentrate. As a proportion of the total Sn, WO_3 and As the quantity would be quite small and the recovery curves indicate that only 25 to 30% of this mineral is recoverable. In a production circuit, the addition of a scavenger stage may be warranted to add robustness to the gravity circuit as plant operation is typically less efficient than can be achieved in a controlled pilot plant environment.

3.6 WET TABLE TESTWORK

Residual cleaner spiral feed (i.e. rougher concentrate received from Amdel) remaining in the spiral feed sump after the completion of release testwork was collected, dried and used as wet table feed. Due to time constraints, the wet table testwork was conducted prior to the assay results from the spiral testwork stages was available. As such, tabling of the residual scavenger spiral feed (rougher middling received from Amdel) was not included.

Two stages of wet table processing were carried out. The cleaner spiral feed was treated in an initial (primary) stage of wet table separation. A sufficiently large concentrate was collected to ensure negligible loss of liberated W and Sn. The table fractions were dried at low temperature, weighed and small sub-samples extracted for assay. Tabling of primary stage middling was not considered necessary.

The primary concentrate was retreated on a secondary (cleaner) stage of wet table separation. In the secondary table stage, bands of Sn (cassiterite) and W (scheelite) were clearly visible. Splitters were set to collect concentrate which contained as much cassiterite as possible without cutting significantly into the scheelite band, in order to produce a high grade Sn concentrate. The middling cut was intended to recover as much of the residual cassiterite and scheelite as possible without cutting into a darker band below the scheelite (presumed to be iron minerals). The table fractions were dried at low temperature, weighed and small sub-samples extracted for assay.

Photos of the primary and secondary wet table stages are presented below.

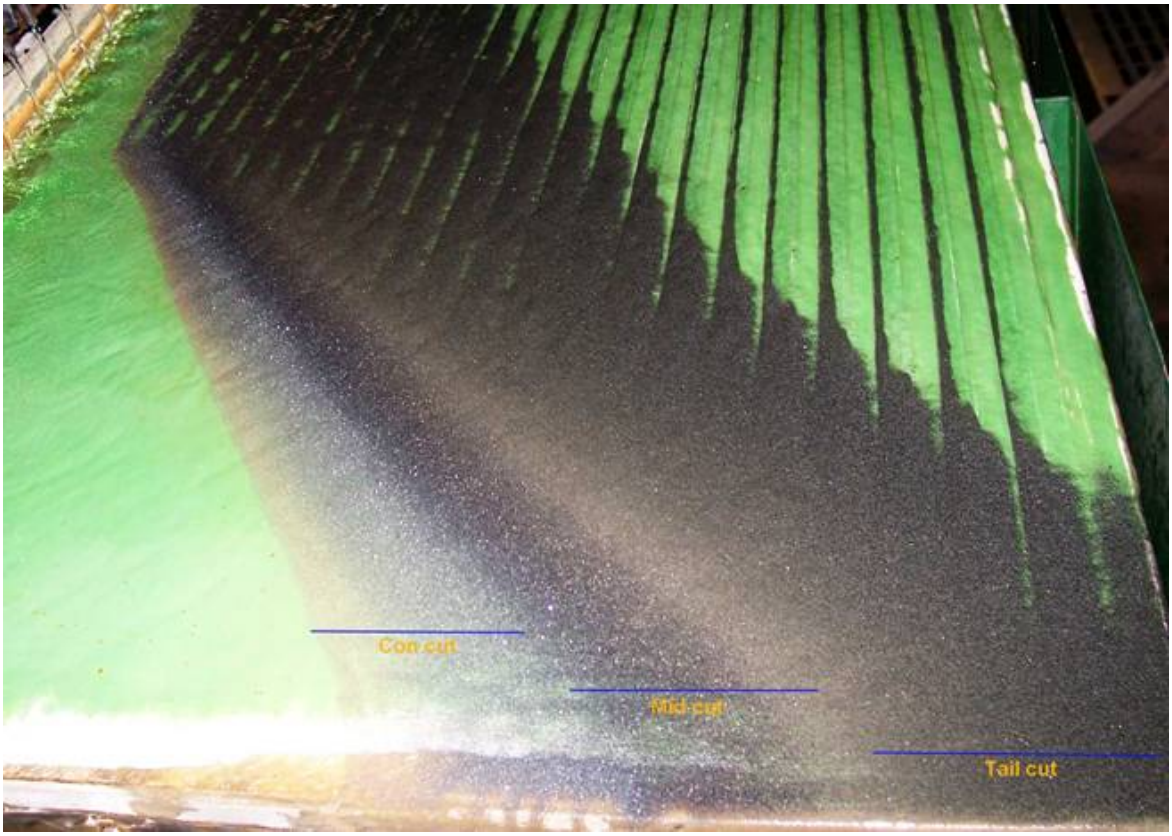

Figure 7: Primary Wet Table Stage Photograph

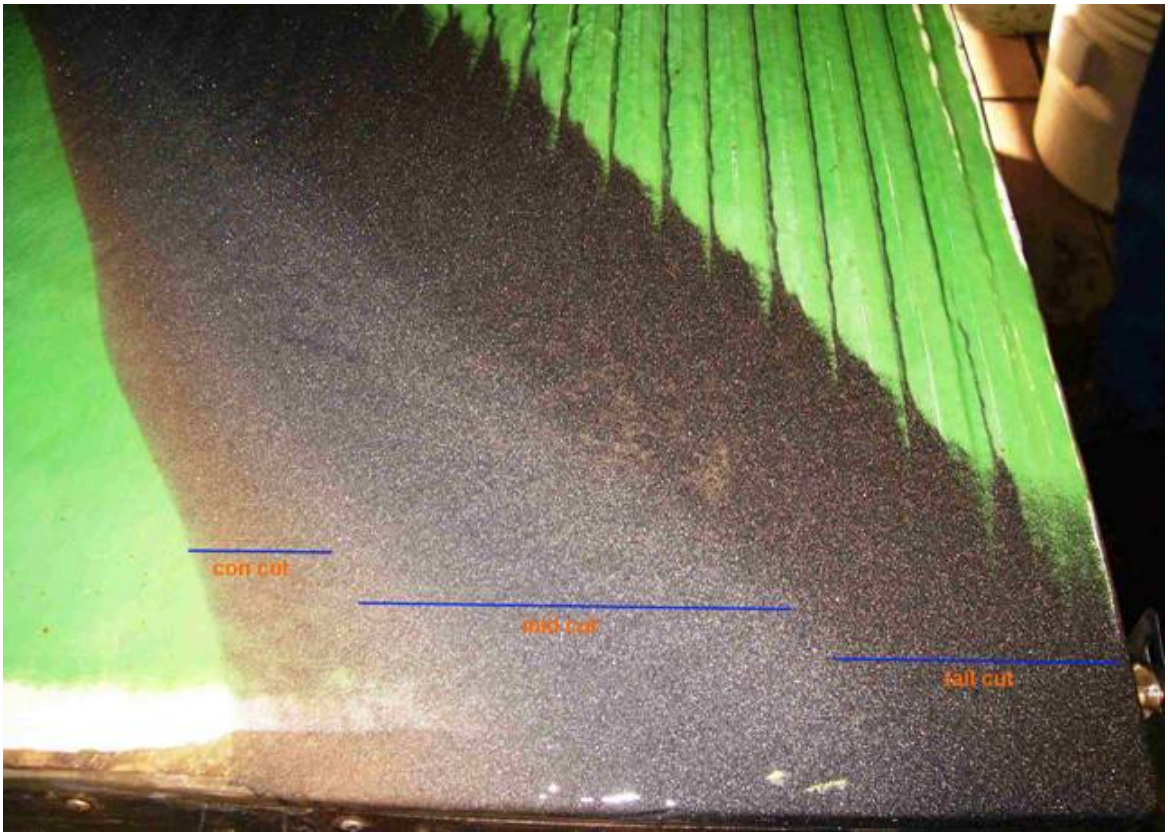

Figure 8: Secondary Wet Table Stage Photograph

The tabulations below present the metallurgical balance for selected assays for the primary and secondary wet table stages treating rougher spiral concentrate produced by Amdel. The full assay balance is presented in the appendices.

Table 1: Primary Wet Table Stage – Mass and Assay Balance

The primary table (test 400) results indicate:

- Effective upgrading of tin, tungsten and sulphide heavy minerals was achieved. The results suggest these minerals were well liberated in the feed. This was expected given that the table feed was a gravity concentrate produced from spiral separation and most unliberated heavy minerals would not have been recovered in the spiral stage.
- A concentrate was produced at a stage mass yield of 11.8% and contained:
  - 12.1% total Sn at a stage recovery of 86.8%
  - 2.13% WO_3 at a stage recovery of 92.3%
  - 4.16% As at a stage recovery of 94.6%
  - 4.95% S at a stage recovery of 49.8%
  - 47.1% Fe at a stage recovery of 23.8%
- Similar recoveries were achieved for Sn and WO_3 using either XRF or ICP assay results with the ICP method reporting a slightly higher assay result in the concentrate for Sn and lower result for WO_3.
- Soluble tin and boron were upgraded in the table concentrate while fluorine mineral was effectively rejected to the tailing stream

Table 2: Secondary Wet Table Stage – Mass and Assay Balance

The secondary (cleaner) table (test 500) results indicate:

- A high grade tin concentrate in excess of 50% Sn was produced confirming the amenability of gravity processes to achieve acceptable upgrading.
- A concentrate was produced at a stage mass yield of 7.7% and contained:
  - 52.9% total Sn at a stage recovery of 33.3%
  - 9.8% WO_3 at a stage recovery of 35.4%
  - 5.9% As at a stage recovery of 10.8%
  - 1.35% S at a stage recovery of 2.1%
  - 10.7% Fe at a stage recovery of 1.8%
- Similar recoveries were achieved for Sn and WO_3 using either XRF or ICP assay results. The ICP method reported a slightly lower assay result for Sn in the concentrate (51.4% Sn compared to 52.9% Sn by XRF) and a significantly lower result for WO_3 (6.7% WO_3 compared to 9.8% WO_3 by XRF).
- Notably, the objective was to produce as high Sn grade as possible in the concentrate. For this reason Sn recovery was relatively low. However the results indicate it was possible to achieve a very high grade concentrate by effectively rejecting sulphide and iron minerals into the middling or tailing streams.
- Soluble tin, boron and fluorine were preferentially rejected to the tailings stream in the cleaner table stage.

3.7 GRAVITY CIRCUIT BALANCES

3.7.1 Wet Table Circuit Balance

A wet table circuit metallurgical balance for selected assays incorporating primary and secondary stages was calculated (based on testwork end streams). The two tabulated mass yields are based on the table circuit feed (spiral concentrate) and spiral feed. A balance including the full assay suite is presented in the appendices

Mass & assay balance			Assays (XRF/UT)										Assays (ICP/UT)			Assays (ICP/SGS)

Table 3: Mass and Assay Balance for Wet Table Circuit

The results for the wet table testwork circuit (treating spiral concentrate) indicate:

- A high grade tin (cassiterite) concentrate containing 52.9% total Sn was produced at a recovery of 29% in a mass yield of 0.91%.
- Tungsten (as scheelite and wolframite minerals) was also effectively upgraded with a table circuit recovery slightly higher than Sn at 32.7%.
- It was possible to achieve a very high grade Sn concentrate by effectively rejecting sulphide and iron minerals into the secondary stage middling and tailing streams.
- Soluble tin, boron were preferentially rejected to the secondary table tailings stream whereas most (80%) of the fluorine mineral was rejected to the primary table tailing.
- Middling and tailing streams are suitable for regrinding and further recovery by flotation methods.

The results were also calculated on a cumulative basis and are presented below.

Table 4: Cumulative Mass and Assay Balance for Wet Table Circuit

The cumulative results for the wet table testwork circuit (treating spiral concentrate) indicate:

- Recovery of 80% of the total Sn and 86% of the WO_3 minerals was achieved in a mass yield of 7.5%.
- The recovery of arsenic (As) minerals (predominantly as arsenopyrite) was similar to Sn and WO_3 at 81% in a mass yield of 7.5% but was shown to be preferentially rejected from the final high grade tin concentrate.

A balance was also prepared to incorporate rougher spiral stage processing (conducted by Amdel) allowing mass yields and recoveries to be calculated for the full gravity circuit. These tables are presented in the appendices.

3.8 ROUGHER SPIRAL FEED CHARACTERISATION

Size analysis was conducted on a sub-sample of the homogenised rougher spiral feed. The sample was wet screened at 45um. The +45um was dried and a sub-sample was screened at 106, 90, 75, and 45um. The -45um from wet screening was filtered and a sub-sample was used for cyclosizer analysis. All size fractions were despatched for assay. The tables below present the assay by size data on incremental (Table 5) and cumulative basis (Table 6) for mass and assay distribution. Fields highlighted in yellow indicate accurate feed grades and distributions could not be calculated due to insufficient sample for assay (IS) for some fractions. These results should be considered as indicative only.

Table 5: Spiral Feed Assay by Size – Incremental Data

The results indicate:

- The grade of total Sn and WO_3 in the sample was 0.44% and 0.09% respectively.
- Sn is distributed throughout the full size range but with notably lower grades contained in the finer size range below 20µm.
- In comparison, WO_3, S and As are more concentrated in the coarser size fractions. 54.6% of the WO_3, 49.3% of the As and 61% of the S are contained in the +106µm fraction compared with 29% of the Sn reporting to this fraction.
- Fe distribution is similar to Sn for the coarse size range but present relatively higher proportions in the finer sizes. The Fe distribution closely follows the mass distribution since Fe minerals make up a large proportion of the sample.
- The elevated grades in the C1 cyclosizer fraction result from the transition of the sizing method from physical aperture (sieve screening above 45µm) to hydraulic sizing (cyclosizing of -45µm). The hydraulic method of involved classification based on the specific gravity of the mineral grains. This can be seen comparing the relative cut sizes for cassiterite and quartz for this fraction. Cassiterite between 45µm and 17µm is recovered to the C1 fraction whereas the quartz recovered to this fraction ranges from 45µm to 31µm resulting in an elevated Sn grade. This is also applicable for other minerals with high specific gravity such as WO_3 (scheelite and wolframite) and sulphide minerals (containing As and S) although the cut size would vary slightly from

the cassiterite cut size. The results also suggest this effect occurred for soluble Sn and boron but not for fluorine.

- There was insufficient sample in the C5 and -C5 cyclosizer fractions to assay for soluble Sn, B and F. Calculated values affected are highlighted in yellow and should be considered as indicative only.
- The soluble Sn, B and F appeared to be fairly even distributed through the sample with slightly lower grades in the courser fractions for soluble Sn and B compared with slightly higher grades in the coarser fractions for F.

Table 6: Spiral Feed Assay by Size – Cumulative Data

The cumulative results indicate:

- 37.9% of the sample is +106µm. The advised grind size P_{80} of 125µm so it is possible the grind was slightly coarser than advised. The proportion of ultrafines (<20µm relative to quartz SG) was very low at less than 7% The size distribution is considered to be very suitable for FM1 spiral and wet table separation.
- 90% of the total Sn and 95% of the WO_3 was coarser than 22µm (relative to cassiterite SG). Cumulative distributions for As and S were similar to WO3. Liberated Sn and WO_3 minerals in this size range should be readily amenable to gravity upgrading.

4. APPENDICES

4.1 APPENDIX 1 – SCOPE OF WORK

A Sample Receipt & Preparation

1 Receive the following Blended Samples (ex flotation and gravity test work at Bureau Veritas – Amdel in Perth) for testwork:
i) ~25kg of FM1 Rougher Spiral Concentrate (nominally -150+15µm) as dewatered slurry (85-90% solids)
ii) ~35kg of FM1 Rougher Spiral Middling (nominally -150+15µm) as dewatered slurry (85-90% solids)
iii) ~75kg of FM1 Rougher Spiral Feed (cyclone U/F) (nominally -150+15µm) as slurry at ~25% solids

2 Separately homogenise each sample and extract sub-samples for:
i) reference (2kg) and head assays (possibly extended suite)
ii) size by grade analysis (Rougher Spiral Feed sample only)
iii) spiral testwork (balance)

B Rougher Spiral Release Testwork (FM1)

1 Conduct assay by size analysis on sub-sample of FM1 Spiral Feed, sizing at 45µm (wet), 45,75, 90 and 106µm (dry) and cyclosizing of -45µm material, and submit all fractions for assays (standard suite)
2 Conduct a series of (3) release tests on rougher FM1 Spiral feed material using FM1 spiral at 1.0-1.2 t/h solids @ 30-35% solids
3 Dry and sub-sample the test fractions and submit for assays (standard suite)
4 Prepare release curves for Sn, WO3 & up to 2 other selected elements recovery & grade vs mass yield

C Cleaner Spiral Release Testwork (FM1)

1 Conduct a series of (3) release tests on rougher FM1 Spiral con material using FM1 spiral at 1.0-1.2 t/h solids @ 30-35% solids
2 Dry and sub-sample the test fractions and submit for assays (standard suite)
3 Prepare release curves for Sn, WO3 & up to 2 other selected elements recovery & grade vs mass yield

D Mid Scavenger Spiral Release Testwork (FM1)

1 Conduct a series of (3) release tests on rougher FM1 Spiral mid material using FM1 spiral at 1.0-1.2 t/h solids @ 30-35% solids
2 Dry and sub-sample the test fractions and submit for assays (standard suite)
3 Prepare release curves for Sn, WO3 & up to 2 other selected elements recovery & grade vs mass yield

E Wet Table Testwork

1 Collect the remaining rougher FM1 Spiral con material, prepare for tabling and sub-sample for assays (standard suite)
2 (If warranted by the results from spiral release tests) collect the remaining rougher FM1 spiral mid material, prepare for tabling and sub-sample for assays (standard suite)
3 Conduct single stage (rougher) testwork on each of these collected feed samples using a Wilfley wet table (1/16 size) to produce con, mid and tail products
4 Dry, weigh and sub-sample rougher table products and submit for assays (standard suite)
5 (if rougher FM1 mid material was processed in the rougher table stage above), proportionally combine the two rougher table con products and the two rougher table mid products for tabling and sub-sample for assays (standard suite)
6 Conduct cleaner (on combined rougher con) and mids scavenger (on combined rougher mid) table testwork using a Wilfley wet table (1/16 size) to produce con, mid and tail products from each stage
7 Dry, weigh and sub-sample cleaner and mid scav table products and submit for assays (standard suite)
8 Combine selected final table products into three bulk products - con, mid and tail - and sub-sample products for assays (possibly extended suite) and possible size by grade analyses

F (Optional) KCJ Tests

1 Run a series of KCJ sighter tests on rougher FM1 spiral feed material under selected conditions, based on assessment of characterisation data and process targets

2 Collect timed feed, concentrate and tailings samples from each test, weigh for mass balancing & submit sub-samples for assays (standard suite)

3 Combine any remaining feed material with reconstituted feed from KCJ sighter tests to form a feed sample for bulk test work, weigh the total mass and collect a head sample for assays (standard suite)

4 Run a KCJ bulk test on the combined feed sample under selected conditions, based on assessment of sighter test results

5 Collect all bulk concentrate (including any material in hutches/ragging bed) and tailings material separately, dry and weigh and submit a sub-sample of each product for assays (possibly extended suite) and possible size by grade analyses

G (Optional) End Stream Assay by Size

1 Conduct assay by size analysis on sub-samples of Combined Table Con, Mid and Tail samples, sizing at 45µm (wet), 45,75, 90 and 106µm (dry) and cyclosizing of -45µm material, and submit all fractions for assays (standard suite)

2 Conduct assay by size analysis on sub-samples of KCJ Bulk Con and Tail samples, sizing at 45µm (wet), 45,75, 90 and 106µm (dry) and cyclosizing of -45µm material, and submit all fractions for assays (standard suite)

H Reporting & Management

1 Prepare technical report including:

i) description of testwork equipment and procedure

ii) tabulated stage spiral and wet table mass and assay data

iii) stage spiral and table performance curves for WO3/Sn grade and recovery versus mass yield

iv) overall mass and assay balance for testwork flowsheet

vi) assay by size analysis of end streams and classification stage

vii) discussion of results, conclusions & recommendations

1.

2. GENERAL

2.1 BACKGROUND

Venture Minerals are working on the development of their Mt. Lindsay tungsten / tin / iron ore project in Tasmania. Previous testwork has been conducted on rougher stage FM1 Spiral Separator Feed, Concentrate and Middling fractions produced from testwork conducted by Bureau Veritas – Amdel in Perth on ore produced from a composite sample of two skarn ores from different areas – MacDonald and Radford Zones. Results from this previous test work program are reported in *Mineral Technologies* report 12/82502/1.

The testwork outlined in this report below was conducted on samples produced from separate processing of the two skarn ore samples mentioned above. The samples tested were "Coarse" Primary Calcite Flotation Tailings streams which were deslimed at nominally 30µm then subjected to gravity separation in China using GZRINM 5-turn spiral separators. The spiral test fractions were dewatered and shipped to *Mineral Technologies* in Queensland for further gravity testwork.

Due to the low mass of the concentrate samples (one from each skarn ore), the fractions were individually separated using a wet shaking table circuit to recover a high grade cassiterite concentrate, with sub-samples of table products being extracted for assays. The plan was to then proportionally recombine the remaining samples to form a single concentrate sample for FM1 spiral release testwork, but this plan was abandoned due to lack of material after consultation with Venture Minerals.

The spiral middling samples (two from each skarn ore) were combined to form a single middling sample for each skarn. With the larger mass available, these samples were processed with an FM1 spiral (release testwork only) and then the remaining / reserve material was separated using a wet shaking table circuit to recover cassiterite.

Further details on the scope of work and results from testing are contained in the sections below.

2.2 MATERIAL

The samples were received by *Mineral Technologies* on 6 June, 2012. The inventory of these samples (with moist weights), as provided by Venture Minerals was:

<u>MAIN SKARN, MacDONALD Zone spiral product</u>

1. SPIRAL CONCENTRATE Conc.1 - 16.5kg
2. SPIRAL Middlings Conc.1,2 - 9.2kg
3. SPIRAL Middlings (2 bags) Mid.1,2 - 44.2kg

<u>#2 SKARN, RADFORD Zone spiral product</u>

1. SPIRAL CONCENTRATE Conc.1 - 6.5kg
2. SPIRAL Middlings Conc.1,2 - 5.8kg
3. SPIRAL Middlings (2 bags) Mid.1,2 - 27.4kg

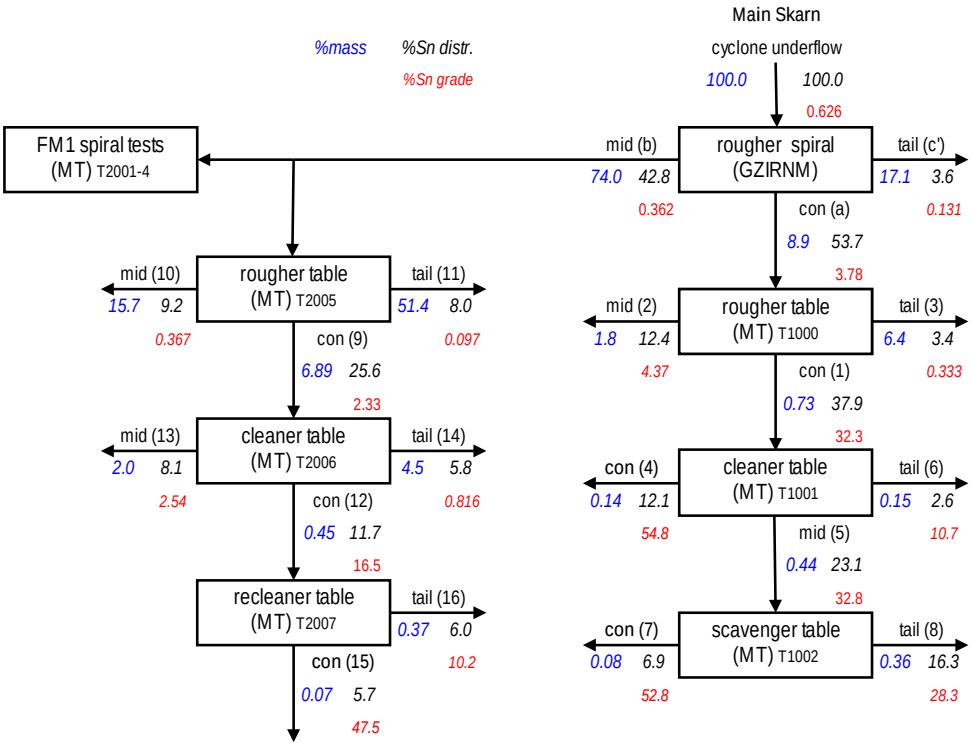
2.3 SCOPE OF WORK

The scope of work was defined in testwork proposal MT MS 12085 rev 1.0, issued 22 June, 2012 and is summarised in Appendix 4.1.

2.4 TERMS OF REFERENCE

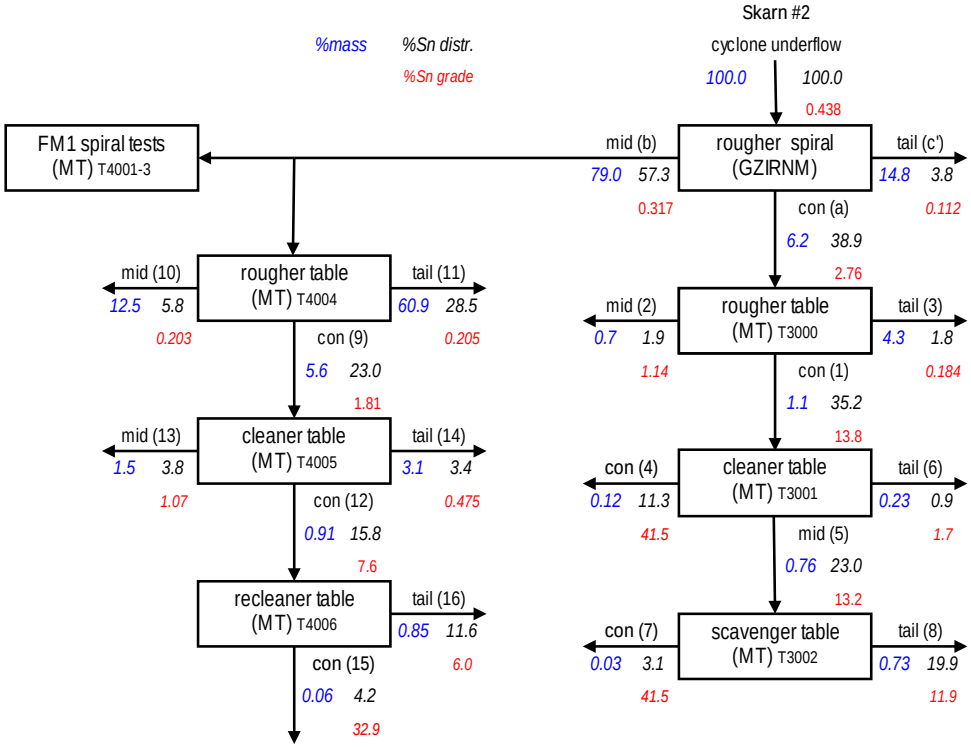
Approval and acceptance of proposal MT MS 12085 rev 1.0 was received from Geoff Beros. Purchase order (#181) was received from Venture Minerals on 22 June, 2012.

2.5 SUMMARY



Venture Minerals are working on the development of their Mt. Lindsay tungsten / tin / iron ore project in Tasmania. Previous testwork has been conducted a composite sample of two skarn ores from different areas – MacDonald and Radford Zones – and results from this previous test work program are reported in *Mineral Technologies* report 12/82502/1.

Samples of spiral concentrate and middlings products from testwork conducted on Venture Minerals – Mt Lindsay "Coarse" Primary Calcite Flotation Tailings material (deslimed at nominally 30µm) using Chinese (GZRINM 5-turn) spiral separators were sent to Mineral Technologies for further gravity separation testwork. Separate product streams were generated from work on material from each of the Main Skarn (MacDonald Zone) and #2 Skarn (Radford Zone) ores.



Based on the relatively low mass of sample available for testing, the majority of the gravity testwork was conducted using a wet shaking table circuit, with the aim being to recover a high grade (>50% Sn) cassiterite concentrate.

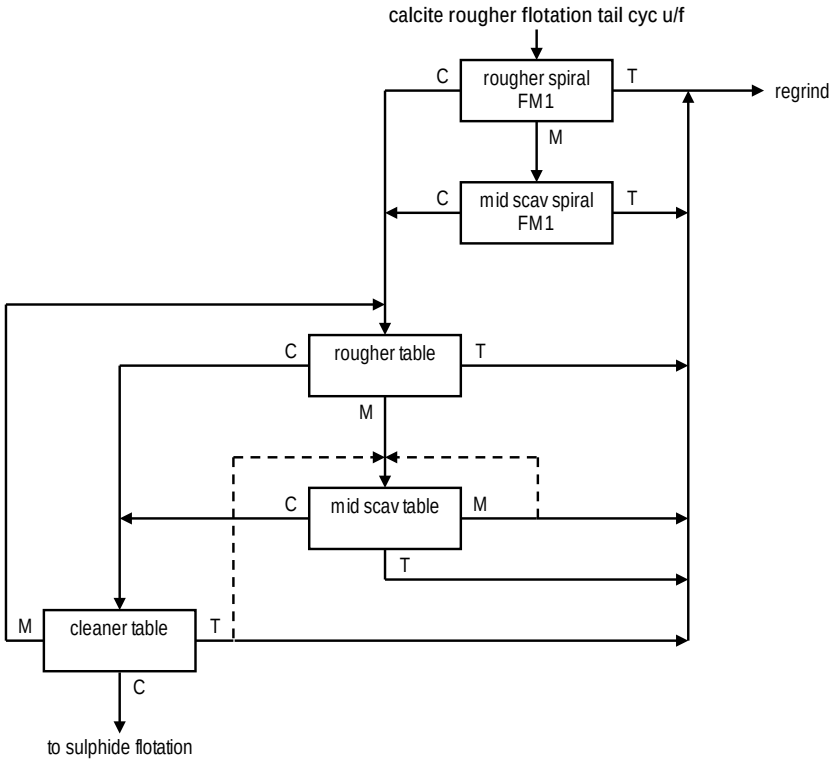
Results from tabling test work are summarised, with respect to mass and Sn distribution and Sn grade, in the flow diagrams below.

MAIN SKARN

#2 SKARN

Overall gravity circuit results were also combined to illustrate cumulative mass and elemental balances relative to Chinese Rougher Spiral Feed (for Sn & WO_3) and/or Con+Mid (for all other elements) and a combination of the three highest grade product streams resulted in the following combined concentrate grades and recoveries:

Ore	Main Skarn			#2 Skarn		
Element	Grade	Recovery		Grade	Recovery	
		(to RS F)	(to RS C+M)		(to RS F)	(to RS C+M)
Sn	52.4	24.6	25.6	39.2	18.7	19.4
WO_3	1.93	25.4	29.3	0.75	4.7	5.2
As	2.61	-	23.6	5.47	-	7.8
Fe	8.32	-	0.1	18.7	-	0.2
S	0.23	-	0.3	2.81	-	0.7
Sol. Sn	0.041	-	0.2	0.009	-	0.1
B	0.088	-	0.2	0.017	-	0.4



For both the Main Skarn and #2 Skarn samples, as recovery of tin to gravity concentrate increased (i.e. including more table streams in the final concentrate), the concentrate Sn, WO_3 and As grades decreased and the Fe, S and B grades increased significantly, due to lower specific gravity (than cassiterite, scheelite and arsenide minerals) iron and sulphide and vonsenite minerals being included in the concentrate.

Some fine mineral (FM1) spiral separation testwork was also conducted on the larger (combination of two) Chinese Rougher Spiral Middlings stream for comparison and results showed that further recovery of liberated tin minerals was possible.

2.6 CONCLUSIONS

Processing of Chinese (GZRINM 5-turn) spiral separator concentrate and middlings products from testwork conducted on Venture Minerals – Mt Lindsay "Coarse" Primary Calcite Flotation Tailings material (deslimed at nominally 30µm) showed that:

- High grade tin concentrates were able to be produced using wet shaking tables
  - Main Skarn – concentrate grade >50% Sn
  - #2 Skarn – concentrate grade ~40% Sn
- The main contaminants in the gravity concentrate and middlings streams are Fe, As and S
  - The grades of these contaminants are all generally higher for the #2 Skarn sample products compared to those from the Main Skarn sample
  - As may be present in the form of arsenide and/or arsenopyrite minerals
- Removal of sulphide minerals, such as arsenopyrite, from gravity concentrates may be possible using flotation
  - This may enable collection of lower grade Sn gravity concentrates at higher Sn recoveries which can then be cleaned using sulphide flotation
- The conceptual process flowsheet (below), with minimal recirculating streams within the table circuit, may be applicable for the gravity separation stages of the Mt Lindsay flowsheet

2.7 RECOMMENDATIONS

- Conduct further processing of selected high grade table circuit products, including sulphide and scheelite flotation
- Conduct further analysis of the table circuit product sub-samples returned to Venture Minerals to determine the characteristics of the Sn minerals in each stream and then:
    - Review the conceptual gravity process flowsheet in terms of potential recirculation of streams which may contain misplaced tin minerals
- Use the information in this report and from further analysis above to define the scope of work for test work on the proposed larger sample of Mt Lindsay "Coarse" Primary Calcite Flotation Tailings material, including:
    - At least two full stages of spiral separation (likely to be rougher and mids scavenger)
    - Three stages of tabling (likely to be rougher, mids scavenger and cleaner) using the largest wet shaking table possible (based on available mass) for each stage to provide a better indication of likely performance at full-scale
    - Reprocessing of selected middlings / tailings streams to enable better estimation of the likely impact on overall tin grade and recovery from the gravity circuit
    - Sulphide and scheelite flotation on larger gravity concentrate samples

The conclusions and recommendations contained within this report pertain to the samples as received, and any variations in feed type or specification, unless specifically addressed are beyond the scope of this report.

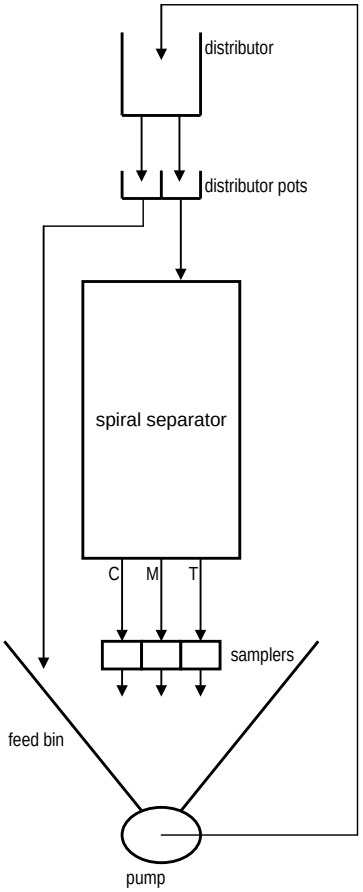
3. TESTWORK PROCEDURE



3.1 WET SEPARATION TESTWORK

3.1.1 Spiral Testwork

All spiral testwork was conducted using a single start full industrial scale spiral separator thereby eliminating scale-up risk between laboratory and commercial operation. The performance achieved in the laboratory is expected to be reproducible in a plant environment at loading per spiral start and feed characteristic similar to those used in the laboratory testwork.

Closed Circuit Operation

- Spiral testwork was conducted in a closed circuit test rig consisting of the test spiral separator (single start), sump, pump and full-stream deflection samplers. The pump discharge reported to a distributor with a portion of the feed stream reporting to the spiral feed box and the remainder returning to the feed sump.
- The spiral feed stream cascades down the spiral trough with the high-density material migrating to the centre column and the low density material being transported to the outer trough. Concentrate splitters recover the high density material to a concentrate channel, whilst intermediate density and low-density streams are directed by further splitters into individual product collection channels within the product collection box. Each stream then returns to the pump sump via timed, full-stream deflection samplers.

closed circuit spiral test rig

- The test rig was started up with water and solids added to the sump until the required test parameters were established.
- For testing of fine feeds, the homogeneous feed was held at the desired pulp density as slurry in an external tank and was transferred to the spiral feed sump as required. The samplers were then operated and the products collected separately.
- The products were weighed wet and then dried. The resultant data were then processed and used to calculate the physical parameters (mass flowrate (t/h) and %solids) of each stream and the feed.
- Sub-samples of each stream were then representatively extracted, using riffle or carousel splitters, for assay purposes.

3.1.2 Wet Shaking Table Testwork

Wet shaking tables employed for the duty were *Holman 2000* (one-quarter of full size) and laboratory-scale *Wilfley* models.

General Procedure

- Dry or dewatered feed was introduced at a constant rate into the feed box and dilution water was added.
- The products were collected into buckets with the aid of manually positioned splitters.
- Products were then dewatered and dried.
- The dried products were weighed and a sub-sample representatively extracted from each using a riffle splitter for assay purposes.
- The *Wilfley* laboratory-scale table was used as an analytical tool and not used for process design testwork. Process design testwork would be based on scaled up data from *Holman* table testwork.

Table Circuit

- Bulk wet table processing was conducted using a circuit comprising feed sump and pump with pump discharge reporting to a distributor with a portion of the feed stream reporting to the wet table feed box and the remains returning to the feed sump.
- New feed was added to the feed sump at an equivalent rate in order to maintain constant operating conditions.

3.2 SAMPLING AND ANALYSIS

3.2.1 Dry Sampling

Dry samples were sub-sampled using a 10-way rotary sampler fed by hopper and vibrating feeder or by a two-way riffle splitter.

3.2.2 Wet Sampling

Sub-samples of slurries were extracted by collecting aliquots of the homogenised slurry. Filter cakes were sub-sampled by extracting a division of the filter cake disc.

3.2.3 Size Analysis

Screening

- Particle size analysis was carried out using 200mm diameter, certified square-mesh test sieves above 38µm aperture.

Cyclosizer Analysis

- Size analysis of -38um material was conducted using a *Warman* Cyclosizer.
- The Warman Cyclosizer is a laboratory precision apparatus for the rapid and accurate determination of particle size distribution within the sub sieve range.

- Each machine is calibrated individually before it leaves the works and typically separates at around 40, 30, 20, 15 and 11 microns
- The Cyclosizer was developed for the mining industry, and a feature of the Cyclosizer separation is that it returns the size fraction for assay of microscopic examination so that information on liberation sizes can be gathered.
- The operation of the Cyclosizer is robust so that although some operator skill is required, it is less sensitive than some other competing processes that do not produce size fractions for examination.
- Particles are separated according to their Stokes equivalent diameter and in this sense differ from say mesh screen sizes, which rely on whether or not a grain will pass a square aperture. Thus, when plotting the sizing results, there is often a small inflection in the graph associated with the change in sizing principle. When Cyclosizer sizing data are plotted against sizing data using other techniques, there is generally a small parallel shift for each technique that is a function of how the technique defines particle size.
- Because the Cyclosizer uses the Stokes equivalent diameter, the fractions produced are specific gravity dependant. It is convention to express the sizings as quartz equivalents, but in reality, these sizings need to be corrected for variations in specific gravity. Corrections are calculated as part of the standard operating technique.
- Although a sizing may use an average specific gravity it is possible for discrete minerals to be classified separately. For instance in the first cyclone that separates at say 40 micron quartz equivalent this will also capture a 14 micron gold grain. Thus heavier minerals report to higher cyclones in the configuration.

3.2.4 Sample Analyses

Ultra Trace (Perth)

- XRF (x-ray fluorescence) and ICP (Inductively Coupled Plasma) chemical analyses were carried out by Ultra Trace Laboratories (Perth, Western Australia).
- Samples for analysis were pulverised in a tungsten carbide ring mill.
- XRF
    - A sub-sample of the pulverised pulp was cast using a 12:22 flux with the addition of sodium nitrate to form a glass bead.
    - The bead was then analysed using X-ray fluorescence spectrometry (XRF) for standard mineral suite analytes.
- ICP
    - A sub-sample of the pulverised pulp was fused with sodium peroxide and subsequently the melt was dissolved in dilute Hydrochloric acid for analysis.
    - Because of the high furnace temperatures, volatile elements are lost.
    - Mo, Sn and W have been determined by Inductively Coupled Plasma (ICP) Mass Spectrometry.

SGS (Townsville)

- Reserve sample pulps from Ultra Trace were also sent to SGS (Townsville, Queensland) for analysis for soluble Sn, B and F.
- Samples were also analysed by ICP method for Sn and WO_3 suite elements for comparison to Ultra Trace results.

3.3 CALCULATIONS AND DEFINITIONS

3.3.1 Mass Balances

Mass balances were conducted for single stage separations using mass of the process streams where possible. In certain circumstances a specific stream mass may be calculated by difference from the feed mass.

Circuit balances were calculated from final end streams and may therefore vary slightly from the individual separation stage balances.

3.3.2 Accuracy and Precision of Measurements

It should be noted that although best practice and care is used for all test work, the data presented is subjected to experimental and analytical errors and hence all data has inherent inaccuracy.

The number of decimal places quoted in this report is used for calculation purposes and clarity only and does not infer any level of accuracy.

3.3.3 Normalising

In order to compare the separation performance of different units or interrogate the optimum feed operating conditions to single units, it is often required to normalise the feed grade for that particular stage. The procedure utilised for normalising the data is as follows:

Adjustment to cumulative weight take

- The most soundly based adjustment to the weight take is to modify the cumulative weight take to successive products in proportion to the alteration in the feed grade.
- This is satisfactory for weight takes less than the feed assay, however, at weight takes in excess of this limit, the adjustment must be made in proportion to the complement of the feed assay (i.e. to the quantity $1 - f$, where f is the feed assay) otherwise predicted weight takes in excess of 100% can be generated.

Adjustment to assay data

- The assay data must also be corrected; however, simply assigning the same upgrade ratio can produce assays in excess of 100%.
- Either recovery (distribution) or separation efficiency parameters could be held constant. There are arguments for and against each alternative; however, it has been found that utilising constant separation efficiency is the most effective.

3.3.4 Separation Efficiency

The basis of the testwork analysis is the calculation of separation efficiency for each test and using the peak efficiency as an indication of the performance.

The concept of efficiency must be interpreted with considerable care. Although qualitative use of the term efficiency is valid and useful, difficulties arise in expressing it quantitatively because two conflicting criteria (grade and recovery) are normally involved in its evaluation. However, the calculation of separation efficiency has been extensively used over the past fifty years and hence is not novel.

Separation efficiency can be defined as the proportion of the original values in the feed that have been recovered in the concentrate in pure form. This is equivalent to the recovery with "dead flux" removed and "normalised" with respect the feed grade.

The formula for the separation efficiency is as follows:

$$E = \frac{R - W}{1 - f}$$

Where R is the component recovery to concentrate
W is yield (mass recovery to concentrate)
f is the fractional feed grade

Using separation efficiency has the effect of normalising for feed grade and the method is therefore particularly useful for direct comparison of different unit performances and for optimisation of feed conditions to single units. The separation that achieves the highest peak is generally deemed the most successful. The feed grade will not affect the peak separation achieved; it will only affect at what mass yield it occurs.

3.3.5 Glossary of Terms and Abbreviations

The following list depicts abbreviations and acronyms of technical terms that may be used throughout the report.

TERM	DESCRIPTION
HM	heavy mineral with specific gravity >2.85 sg
LM	light mineral with specific gravity <2.85 sg
VHM	very heavy mineral of +4.05 sg, which includes zircon, monazite, TiO_2 minerals such as primary ilmenite & rutile
LHM	light heavy minerals in the +2.85 to –4.05 sg range, which may include TiO_2 minerals such as altered ilmenite, leucoxene and pseudo-rutile May be further sub-divided (commonly at 3.6 sg) for more specific profiling of TiO_2 minerals.
HMC	heavy mineral concentrate (generally wet plant final product)
O/F	overflow
U/F	underflow
>	greater than
<	less than

HLS	heavy liquid separation
Spiral	spiral separator
s.g / SG	specific gravity
conc.	concentrate
mid	middling
tail	tailing
slime tail	generally refers to the overflow fraction of a bulk tailing that has been classified or dewatered
sand tail	generally refers to the underflow fraction of a bulk tailing that has been classified or dewatered
core	sub-sample taken from a drum of sample using an auger or other spearing device
wt % stage	mass distribution for an individual stage of separation or processing
wt % head	mass distribution calculated from the feed to a defined multi stage circuit
w/w	ratio or proportion based on two masses
cyclone	hydrocyclone
bleedout	processing of a bulk sample through an open circuit test rig
sighter test	small size timed samples of spiral products in a closed circuit test rig.
spiral release curves	mass yield versus mineral recovery, separation efficiency or grade for a specified analyte at a selected operating condition
KPI	Key Performance Indicator such as plant feed rate, HMC target grade, WGC recoveries,

4. RESULTS AND DISCUSSIONS

4.1 MAIN SKARN (MACDONALD ZONE) SAMPLES

4.1.1 Testwork Flow Diagram (Main Skarn Sample)

The flow diagram in Figure 1 below depicts the actual testwork conducted on the Main Skarn samples.

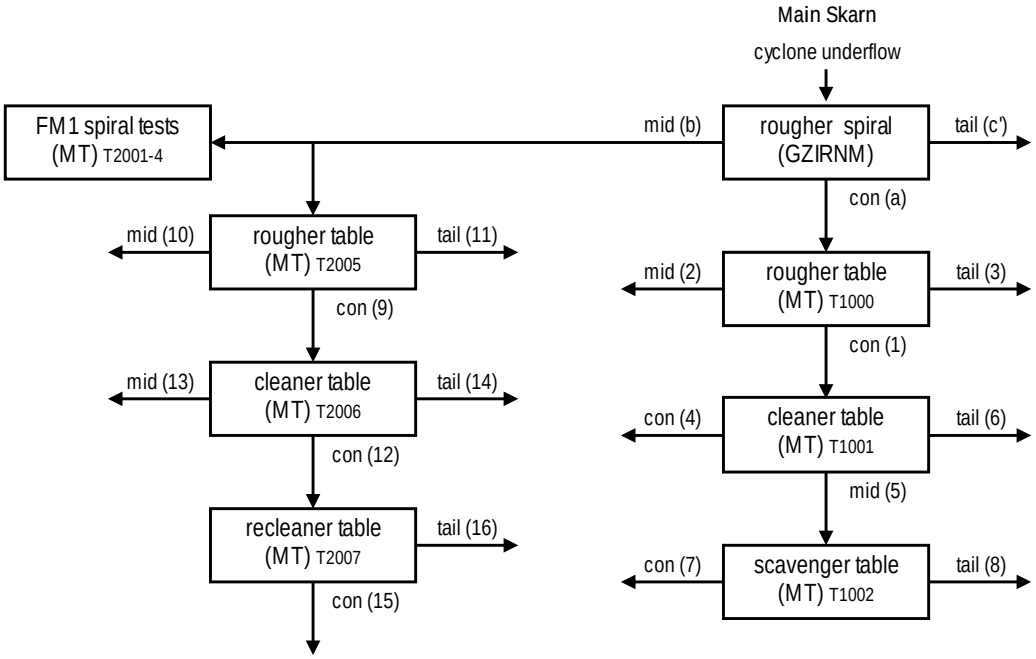


Figure 1: Testwork Flow Diagram – Main Skarn Sample

4.1.2 Wet Shaking Table Testwork on Rougher Spiral Concentrate (T1000-2)

The Rougher Spiral Concentrate sample was initially processed through a rougher stage of wet shaking table separation. Figure 2 below shows a photo of the rougher stage, illustrating the clear bands of minerals formed during the separation. The heaviest light brown band is assumed to be cassiterite, while the next heaviest dark grey band is assumed to contain a combination of scheelite and iron minerals. Splitters were set to collect a sufficiently large concentrate sample to ensure negligible loss of liberated Sn and W minerals, so tabling of rougher stage middlings was not considered necessary.

The rougher concentrate was then reprocessed through a cleaner stage of wet shaking table separation, in which there was clearly a band of Sn (cassiterite), but bands of W (scheelite) and iron minerals appeared less distinctive (see Figure 3 below). Splitters were set to collect concentrate which contained as much cassiterite as possible without cutting significantly into the scheelite / iron mineral band, in order to produce a high grade Sn concentrate.

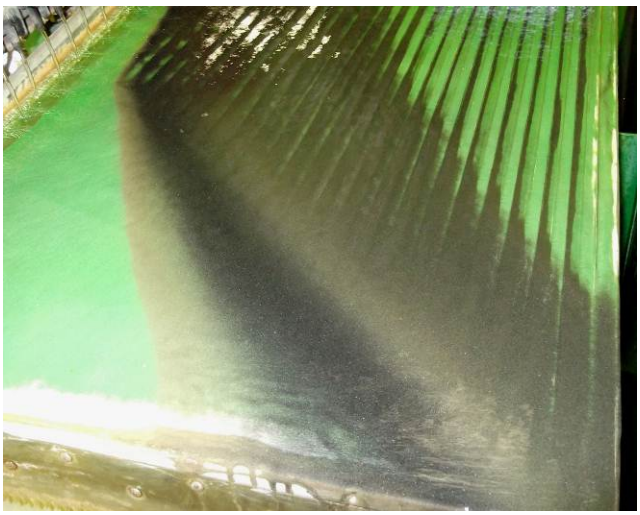

Figure 2: Rougher Table Testwork (T1000)

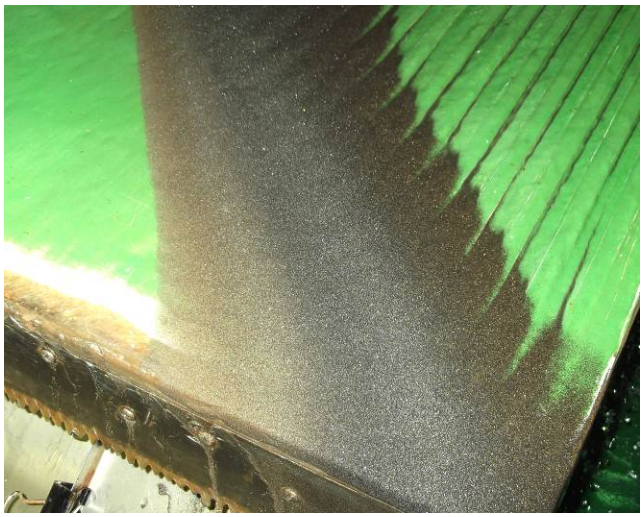

Figure 3: Cleaner Table Testwork (T1001)

With what appeared to be a relatively low level of scheelite mineral acting as a buffer between the cassiterite and iron minerals in the cleaner stage (see Figure 3 above), a third (scavenger) stage of tabling was conducted on the cleaner table middlings fraction to ensure maximum recovery of cassiterite which may have been collected in this middlings fraction. Figure 4 below shows a photo of this scavenger stage, clearly showing that there was sufficient cassiterite in the middlings stream to warrant the scavenger stage. Splitters were set to collect a high grade cassiterite concentrate.

All table fractions were dried at low temperature, weighed and small sub-samples extracted for assay.

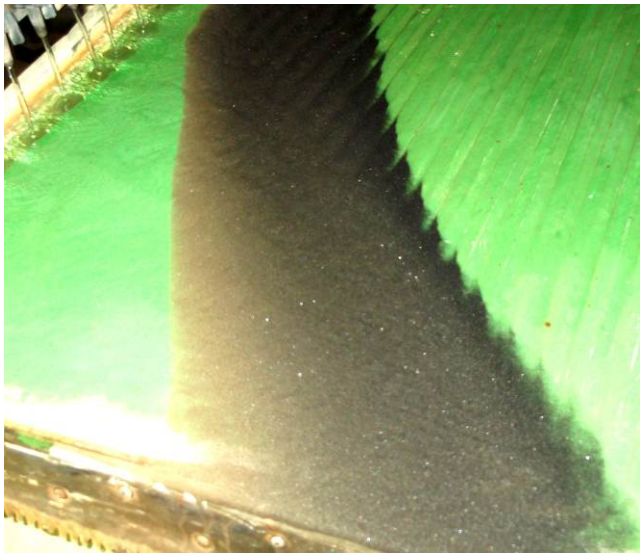

Figure 4: Scavenger Table Testwork (T1002)

The tabulations below present the metallurgical balance for selected assays for the three stages of wet shaking table separation on Main Skarn Rougher Spiral Concentrate material. The full assay balances are presented in Appendix 4.2.

The rougher table (Test 1000) results are summarised in Table 1 below.

Table 1: Rougher Table Testwork – Mass and Assay Balances (T1000)

The rougher table (Test 1000) results indicate:

- Effective upgrading of tin, tungsten and arsenic heavy minerals was achieved, suggesting that these minerals were well liberated in the feed, which was to be expected given that the table feed was a gravity concentrate produced from spiral separation and most unliberated heavy minerals would not have been recovered in the spiral stage

- A concentrate was produced at a stage mass yield of 8.3% and contained:
    - 36.2% total Sn at a stage recovery of 72.9%
    - 1.08% WO_3 at a stage recovery of 77.2%
    - 2.27% As at a stage recovery of 76.5%
- S and Fe minerals were concentrated into the middlings fraction with some residual Sn, W and As minerals not captured in the concentrate
- Soluble Sn and B (vonsenite) minerals were concentrated into the middlings fraction, which is in line with the specific gravity (~4.1) of vonsenite
- >95% of the F minerals were rejected to the table tailings stream
- The high recovery of As without a high recovery of S is likely to be due to the presence of arsenide, which behaves similarly to arsenopyrite, but does not contain S (as reported by Venture Minerals)
- Some calculated feed assays did not correlate well with head assays (as highlighted in Table 1 above)
    - The discrepancy with Ca assays is possibly associated with calibration issues due to a wide variation in Ca grades between table products
    - The discrepancy with B assays is possibly associated with the behaviour of vonsenite

The cleaner table (Test 1001) results are summarised in Table 2 below.

The cleaner table (Test 1001) results indicate:

- A high grade (>50% Sn) tin concentrate was produced at a stage mass yield of 18.8% and contained:
    - 54.8% total Sn at a stage recovery of 32%
    - 2.06% WO_3 at a stage recovery of 35.9%
    - 2.66% As at a stage recovery of 23.4%

- A significant proportion of Sn, W, Fe, S and As minerals were concentrated into the middlings fraction, supporting the decision to re-process this stream as outlined above
- Soluble Sn and B (vonsenite) minerals were mainly concentrated into the tailings stream, while being predominantly distributed into the middlings fraction with the bulk of the mass
- >85% of the F minerals were rejected to the table middlings and tailings streams

The scavenger table (Test 1002) results are summarised in Table 3 below.

The scavenger table (Test 1002) results indicate:

- A high grade (>50% Sn) tin concentrate was produced at a stage mass yield of 18.4% and contained:
  - 52.8% total Sn at a stage recovery of 29.7%
  - 1.55% WO_3 at a stage recovery of 28.8%
  - 2.41% As at a stage recovery of 20.2%
- Further rejection of soluble Sn and B (vonsenite) minerals was achieved
- Distribution of F minerals to table product streams was effectively in line with mass distributions

The overall results from the combined rougher, cleaner and scavenger table circuit are shown in Appendix 4.2 and summarised Table 4 below.

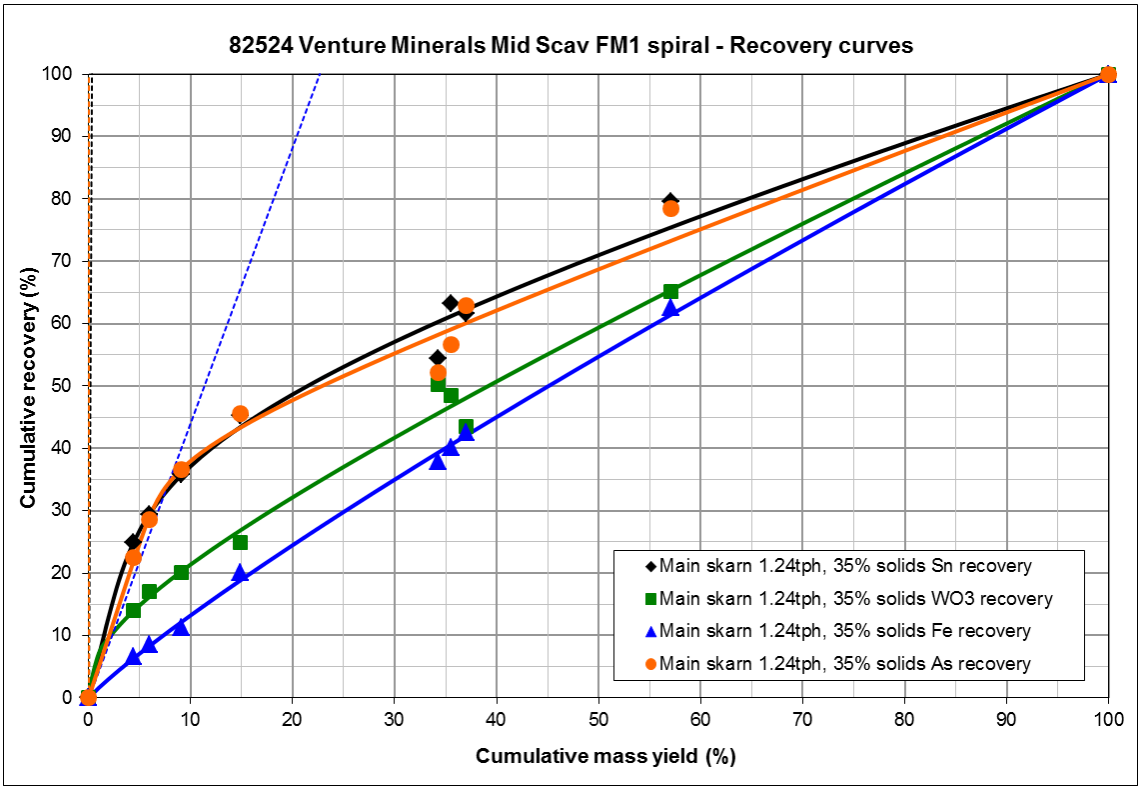
The overall results from the combined rougher, cleaner and scavenger table circuit indicate:

- Combination of cleaner and scavenger stage concentrates would produce a high grade (>50% Sn) tin concentrate at a table circuit stage mass yield of 2.47% and containing:
    - 54.1% total Sn at a table circuit stage recovery of 35.3%
    - 1.87% WO_3 at a table circuit stage recovery of 40%
    - 2.57% As at a table circuit stage recovery of 27.1%
    - 6.48% Fe at a table circuit stage recovery of 0.6%
    - 0.09% S at a table circuit stage recovery of 0.3%
    - 0.032% soluble Sn at a table circuit stage recovery of 0.6%
    - 0.066% B at a table circuit stage recovery of 0.6%

4.1.3 FM1 Spiral Separator Testwork on Rougher Spiral Middlings (T2001-4)

With the larger amount of sample available, a series of four release tests were carried out using a fine mineral spiral (FM1 – 6.5 turn version) to determine potential performance in a scavenger stage processing Chinese Rougher Spiral Middlings material.



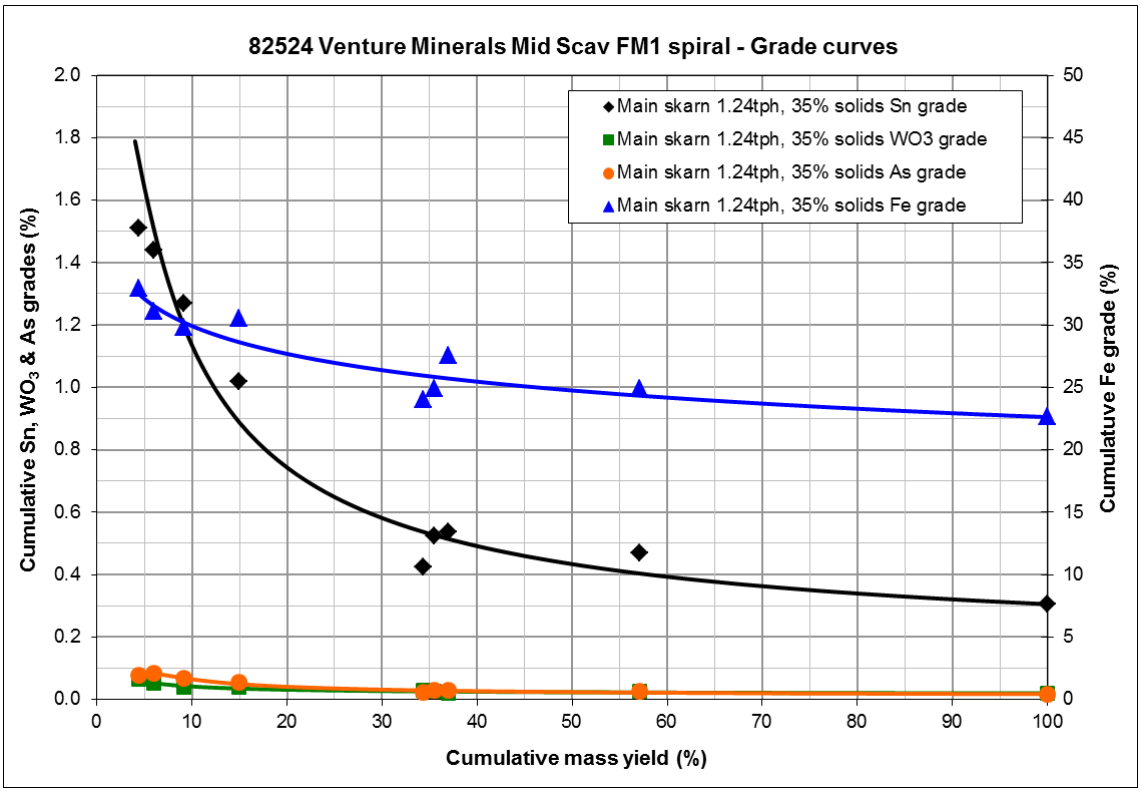
All tests were conducted at a target feed rate of approximately 1.2 t/h @ 30-35% solids. Splitters were adjusted between tests to vary the concentrate, middling and tailing mass yields. The test fractions were weighed wet, dried at low temperature (<70^{o}C) and re-weighed. Sub-samples of each test fraction were extracted for assay.

The mass flow and assay data were tabulated for each test and are presented in Appendix 4.3. Release curves for tin (Sn), tungsten (WO_3), iron (Fe), arsenic (As), soluble tin (sol Sn), boron (B) and fluorine (F) were delineated from the test data. The release curves for recovery and grade versus mass yield are presented below in Figure 5 and Figure 6 below. For clarity Sn, WO_3, Fe and As curves are presented in separate charts from the soluble Sn, B and F. The release curves for separation efficiency are presented in Appendix 4.3.

The recovery and grade curves in Figure 5 and Figure 6 below and the detailed data in Appendix 4.3 show:

- Some upgrading of Sn, WO_3 and As minerals was achieved at recoveries of approximately 4% mass, 30% Sn, 15% WO_3 and 30% As, suggesting that a reasonable amount of liberated tin minerals were present in the Chinese Rougher Spiral Middlings material
- The feed contained ~0.3% Sn (~0.07% soluble Sn) and a concentrate containing approximately 1.5% Sn (~0.17% soluble Sn) was achieved at a concentrate mass yield of ~4%
- While some upgrading of W minerals to concentrate did occur, the feed contained only ~0.02% WO_3, suggesting most of the liberated scheelite had been recovered to Chinese Rougher Spiral Concentrate
- For concentrate mass yields >5% the Sn & As recovery curve gradients reduce significantly, indicating poor separation and limited upgrading of the remaining Sn and As minerals, most likely due to them being very fine, coarse or unliberated
- The recoveries for Fe, soluble Sn and B were only marginally higher than the mass yield indicating poor response to gravity upgrading by spirals
- The F data points were very scattered and it was not possible to define a grade curve, but the data does indicate a slight downgrading of F into spiral concentrate

Given the aim of a rougher spiral mids scavenging stage such as this one would be to maximise recovery of liberated Sn minerals, while also reducing the amount of material going to downstream cleaning with wet shaking tables, a concentrate mass yield slightly greater than that at which optimum separation efficiency is achieved would like be targeted. In this case, a concentrate mass yield of ~20-25% may be targeted, which would result in recovery of ~50% Sn, ~50% As and ~30% WO_3 to a concentrate containing ~0.7% Sn, ~0.03% As and ~0.02% WO_3.



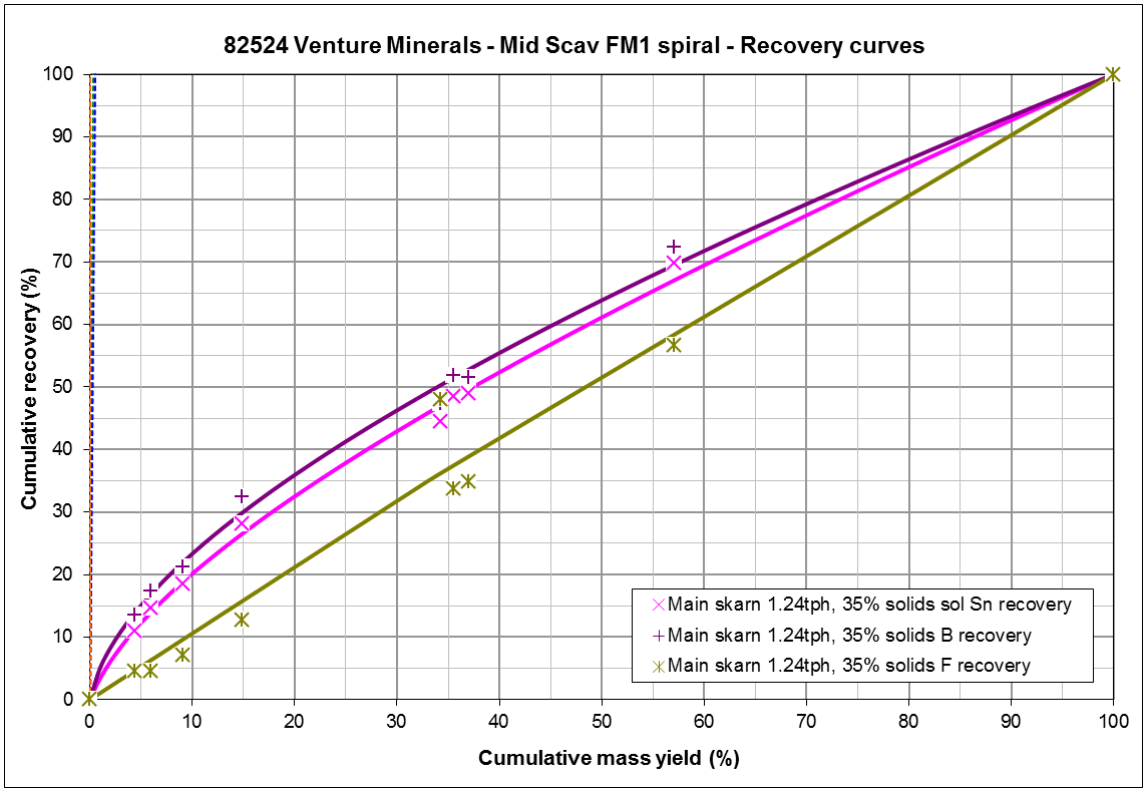


Figure 5: Scavenger Spiral Recovery & Grade Curves for Sn, WO_3, Fe & As (T2001-4)

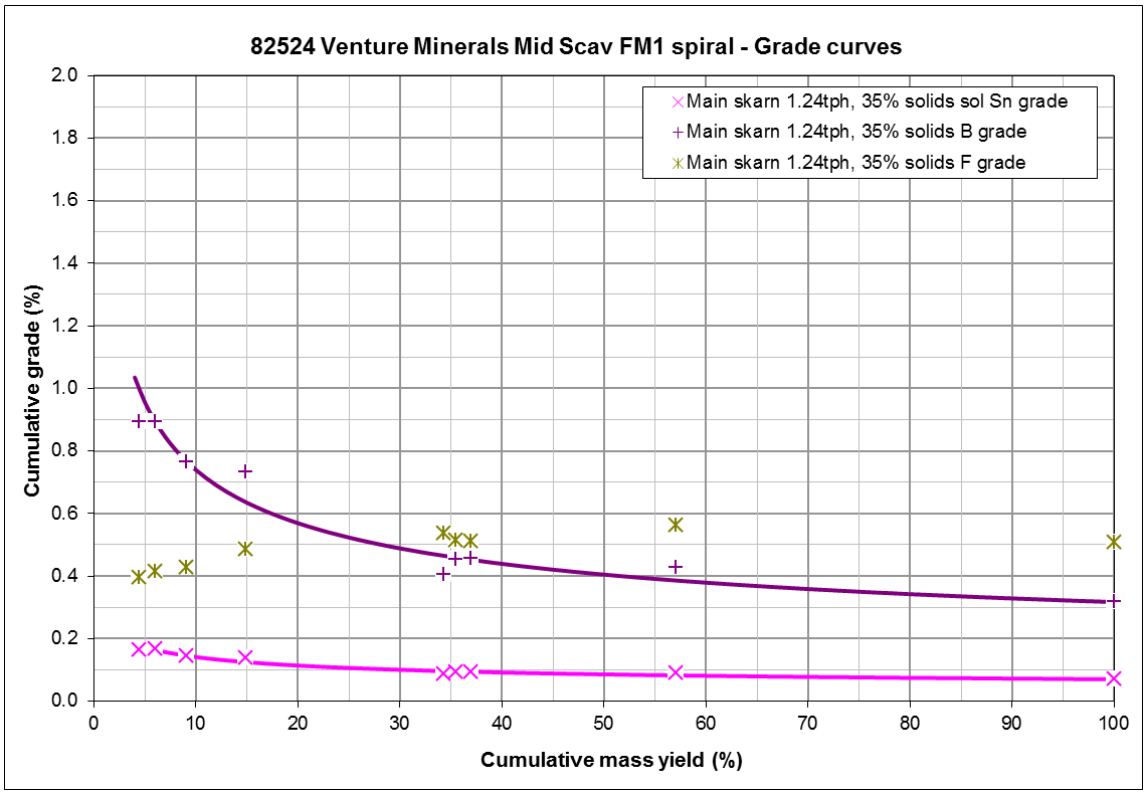

Figure 6: Scavenger Spiral Recovery & Grade Curves for soluble Sn, B & F (T2001-4)

4.1.4 Wet Shaking Table Testwork on Rougher Spiral Middlings (T2005-7)

The Rougher Spiral Middlings sample was initially processed through a rougher stage of wet shaking table separation. The rougher concentrate was then reprocessed through a cleaner stage of wet shaking table separation, in which a narrow band of Sn (cassiterite) was observed, along with a dark grey band of most likely W (scheelite) and iron minerals (see Figure 7 below). Splitters were set to collect concentrate which contained as much cassiterite as possible without cutting significantly into the scheelite / iron mineral band, in order to produce a high grade Sn concentrate.

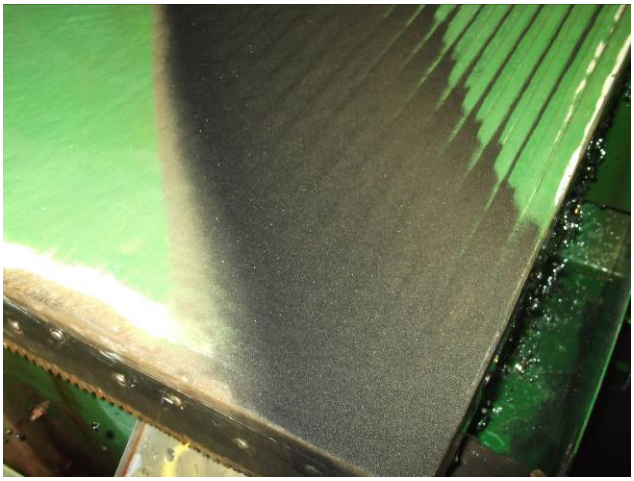

Figure 7: Cleaner Table Testwork (T2006)

With the aim being to produce a high grade tin concentrate, the third stage of tabling for this sample was run on the cleaner stage concentrate as a re-cleaner stage to determine whether more high grade concentrate could be produced from the rougher spiral middlings stream. Figure 8 below shows a photo of this re-cleaner stage, clearly showing a distinctive band of high grade cassiterite, which splitters were set to collect.

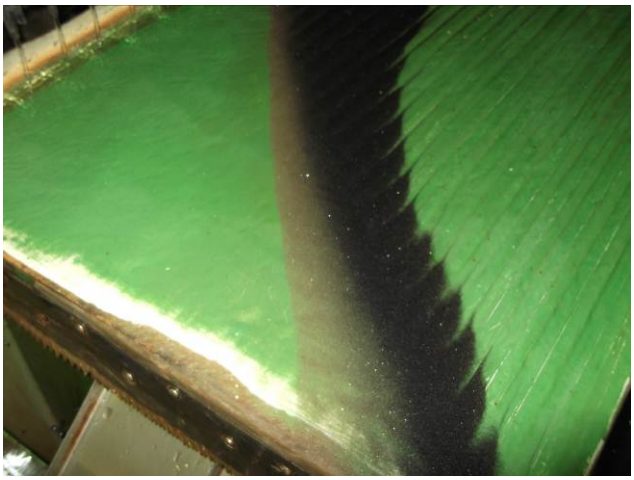

Figure 8: Re-Cleaner Table Testwork (T2007)

All table fractions were dried at low temperature, weighed and small sub-samples extracted for assay.

The tabulations below present the metallurgical balance for selected assays for the three stages of wet shaking table separation on Main Skarn Rougher Spiral Middlings material. The full assay balances are presented in Appendix 4.4.

The rougher table (Test 2005) results are summarised in Table 5 below.

Table 5: Rougher Table Testwork – Mass and Assay Balances (T2005)

The rougher table (Test 2005) results indicate:

- Effective upgrading of tin, tungsten and arsenic heavy minerals was achieved (with similar concentrate upgrade ratios to those achieved in rougher table tests on rougher spiral concentrate material), suggesting that a reasonable amount of these minerals were still liberated in the rougher spiral middlings material
- A concentrate was produced at a stage mass yield of 9.3% and contained:
    - 3.3% total Sn at a stage recovery of 68%
    - 0.084% WO_3 at a stage recovery of 67.4%
    - 0.17% As at a stage recovery of 73.8%
- 68.2% of S minerals and 20.2% of Fe minerals were also recovered and upgraded to the concentrate stream, possibly suggesting that the rougher spiral middlings contained a higher proportion of heavy sulphide minerals, such as pyrite and/or arsenopyrite
- Soluble Sn and B (vonsenite) minerals were concentrated mainly into the concentrate fraction, due most likely to the lower level of cassiterite and scheelite minerals, i.e. the vonsenite was concentrated with the cassiterite, scheelite and S minerals
- ~78% of the F minerals were rejected to the table tailings stream
- Some calculated feed assays again did not correlate well with head assays (as highlighted in Table 5 above)

The cleaner table (Test 2006) results are summarised in Table 6 below.

The cleaner table (Test 2006) results indicate:

- A reasonably high grade tin concentrate was produced at a stage mass yield of 6.5% and contained:
    - 15.9% total Sn at a stage recovery of 45%
    - 0.48% WO_3 at a stage recovery of 37.3%
    - 0.92% As at a stage recovery of 56.6%
- A significant proportion of Fe and S minerals, likely to be in the form of iron sulphide minerals such as pyrite, were rejected to the middlings and tailings fractions
- Soluble Sn and B (vonsenite) minerals were mainly concentrated into the middlings stream, while being predominantly distributed into the tailings fraction with the bulk of the mass
- The high recovery of As without a high recovery of S is likely to be due to the presence of arsenide, which behaves similarly to arsenopyrite, but does not contain S (as reported by Venture Minerals)
- >98% of the F minerals were rejected to table middlings and tailings streams

The re-cleaner table (Test 2007) results are summarised in Table 7 below.

The re-cleaner table (Test 2007) results indicate:

- A high grade tin concentrate was produced at a stage mass yield of 16.8% and contained:
  - 47.5% total Sn at a stage recovery of 48.4%
  - 2.09% WO_3 at a stage recovery of 58.5%
  - 2.73% As at a stage recovery of 44.2%
- Further rejection of soluble Sn and B (vonsenite) minerals was achieved
- Distribution of F minerals to table product streams was approximately in line with mass distributions, with a slight upgrade to the concentrate stream

The overall results from the combined rougher, cleaner and re-cleaner table circuit are shown in Appendix 4.4.

4.1.5 Overall Gravity Circuit Balances (Main Skarn Sample)

The overall gravity circuit mass and tin balances for the Main Skarn sample, relative to the Chinese Rougher Spiral Feed, are shown in Figure 9 below.

The data for the Chinese Rougher Spiral stage was supplied by Venture Minerals and is attached in Appendix 4.10 for reference.

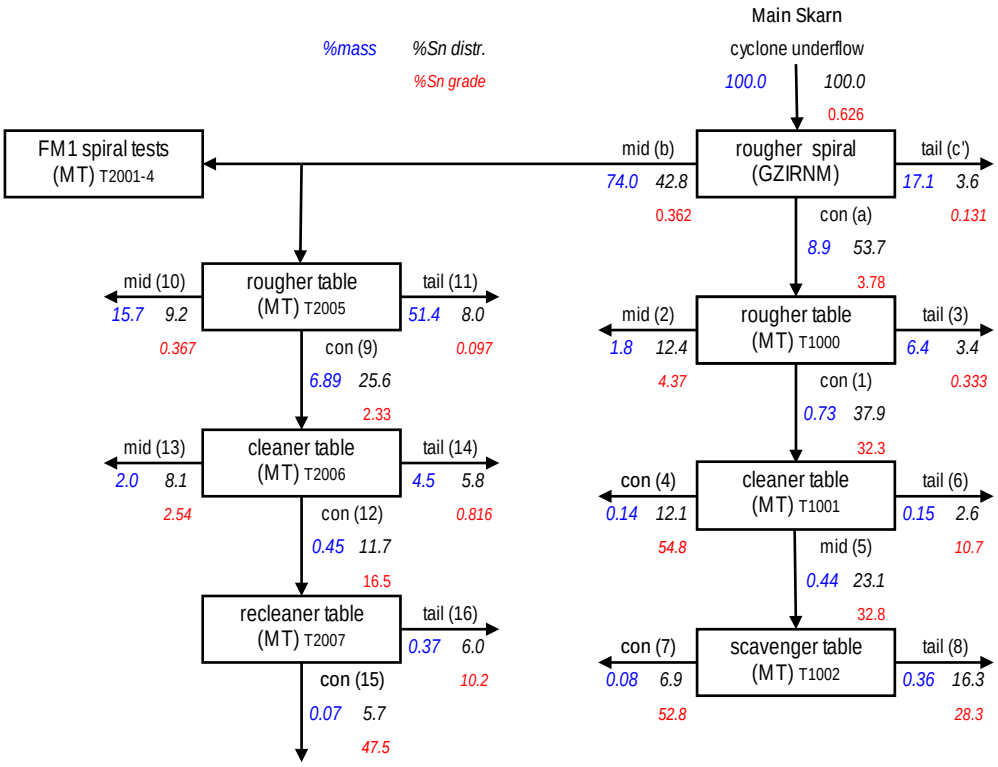

Figure 9: Overall Gravity Circuit Mass and Tin Balances – Main Skarn Sample

The overall gravity circuit results have also been combined to illustrate cumulative mass and elemental balances relative to Chinese Rougher Spiral Feed (for Sn & WO_3) and/or Con+Mid (for all other elements). This data is presented in detail in Appendix 4.5, while Table 8 below summarises the data for key elements and Figure 10 below illustrates the cumulative gravity circuit concentrate grade (for key elements) versus cumulative Sn recovery to concentrate.

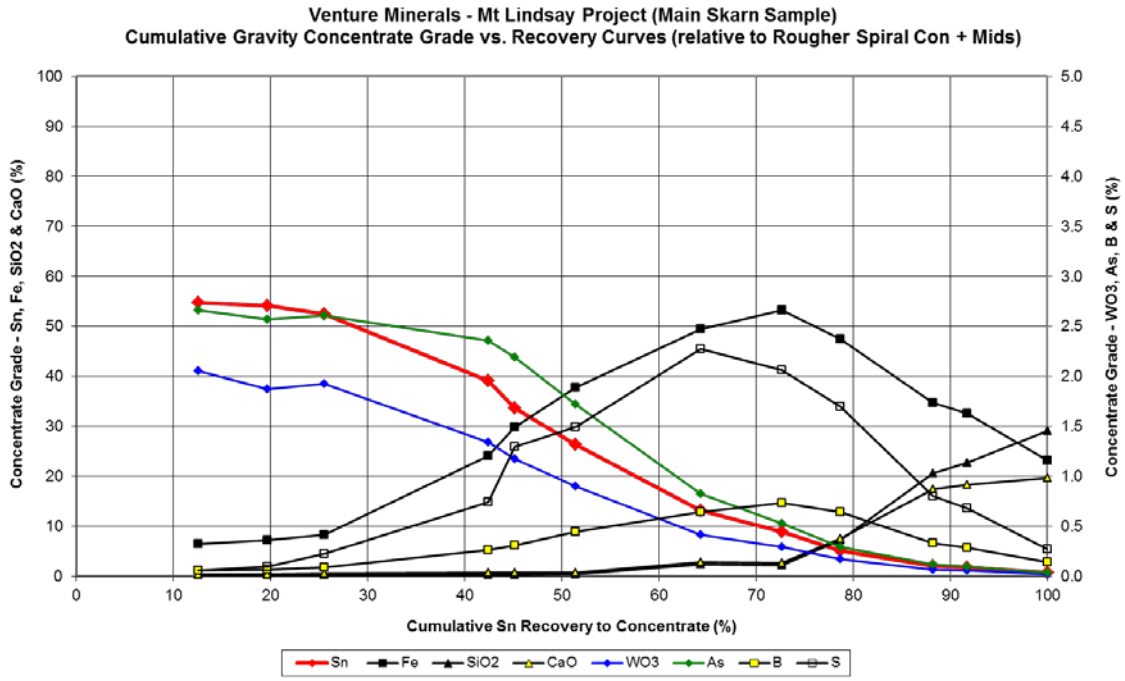

Figure 10: Cumulative Gravity Circuit Concentrate Grade vs Sn Recovery (Main Skarn)

The data in Table 8 above and Figure 10 above show that:

- Combination of cleaner con (4), scavenger con (7) and re-cleaner con (15) would produce a high grade (>50% Sn) tin concentrate at an overall gravity circuit stage mass yield of 0.29% and containing:
    - 52.4% total Sn at a gravity circuit recovery of 24.6% (25.6%[1])
    - 1.93% WO_3 at a gravity circuit recovery 25.4% (29.3%[1])
    - 2.61% As at a gravity circuit recovery 23.6%[1]
    - 8.32% Fe at a gravity circuit recovery 0.1%[1]
    - 0.23% S at a gravity circuit recovery 0.3%[1]
    - 0.041% soluble Sn at a gravity circuit recovery 0.2%[1]
    - 0.088% B at a gravity circuit recovery 0.2%[1]
- As recovery of tin to gravity concentrate increases (past approximately 25%), the concentrate Sn, WO_3 and As grades decrease steadily, while the Fe and S grades steadily increase, suggesting that additional tin in the lower grade gravity circuit streams has either been misplaced (not captured into the high grade concentrate streams) or is not fully liberated
- The increase in recovery of Fe, S and B to concentrate is consistent with the lower specific gravity (than cassiterite, scheelite and arsenide minerals) iron and sulphide and vonsenite minerals being rejected to table circuit middlings streams
- The main contaminants in the lower grade gravity circuit streams appear to be Fe, S and As, so depending on what mineralogical form these minerals are present in, it may be possible to increase recovery of Sn by including these streams in the gravity circuit concentrate and subjecting them to flotation to remove the sulphide (possibly arsenopyrite) minerals
    - Removal of these Fe/S minerals from spiral circuit concentrates, prior to cleaning on wet shaking tables, may have some benefit in that these minerals would not compete for a place in the table circuit concentrate and Sn recoveries may improve
    - However, feedback from Venture Minerals suggests that their preferred approach may be to allow the sulphide minerals to build up in the gravity circuit and then remove them using flotation

[1] Relative to Chinese Rougher Spiral concentrate + middlings

4.2 #2 SKARN (RADFORD ZONE) SAMPLES

4.2.1 Testwork Flow Diagram (#2 Skarn Sample)

The flow diagram in Figure 11 below depicts the actual testwork conducted on the Main Skarn samples.

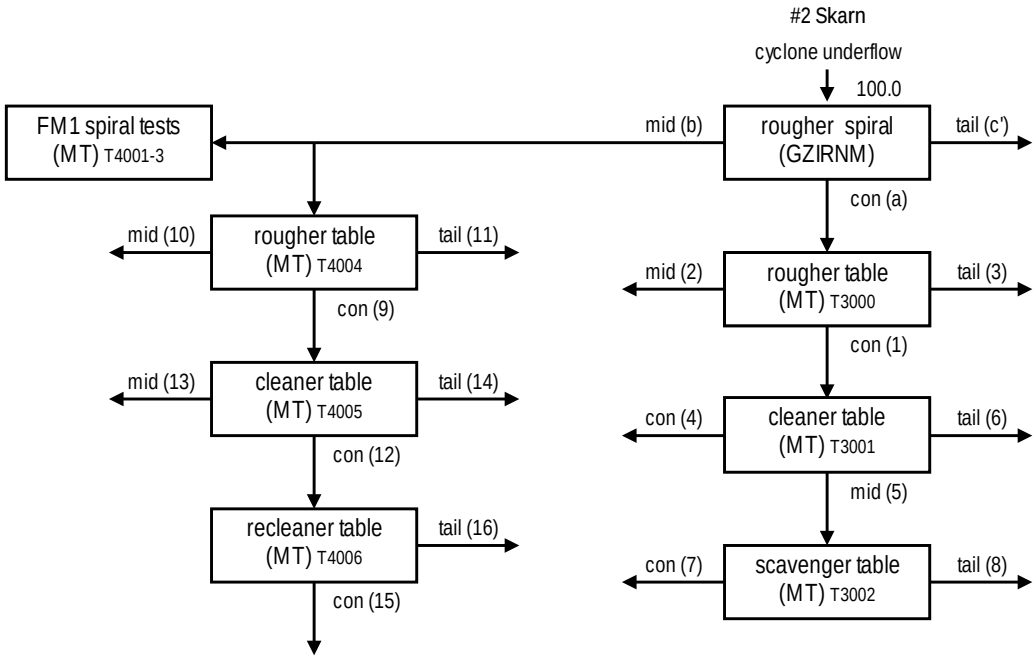

Figure 11: Testwork flow diagram – #2 Skarn Sample

4.2.2 Wet Shaking Table Testwork on Rougher Spiral Concentrate (T3000-2)

The Rougher Spiral Concentrate sample was initially processed through a rougher stage of wet shaking table separation. Figure 12 below shows a photo of the rougher stage, illustrating the reasonably distinctive bands of minerals formed during the separation. The heaviest light brown band is again assumed to be cassiterite, but there appears to be far less of the next heaviest dark grey band (assumed to contain a combination of scheelite and iron minerals) for this Skarn #2 sample compared to the Main Skarn sample (see Figure 2 above). Splitters were set to collect a sufficiently large concentrate sample to ensure negligible loss of liberated Sn and W minerals, so tabling of rougher stage middlings was not considered necessary.

The rougher concentrate was then reprocessed through a cleaner stage of wet shaking table separation, in which there was clearly a band of Sn (cassiterite), but bands of W (scheelite) and iron minerals appeared less distinctive and there also appeared to be a lighter beige coloured band of fine heavy mineral which may be fine cassiterite (see Figure 13 below). Splitters were set to collect concentrate which contained as much cassiterite as possible without cutting significantly into the scheelite / iron mineral band, in order to produce a high grade Sn concentrate.

Figure 12: Rougher Table Testwork (T3000)

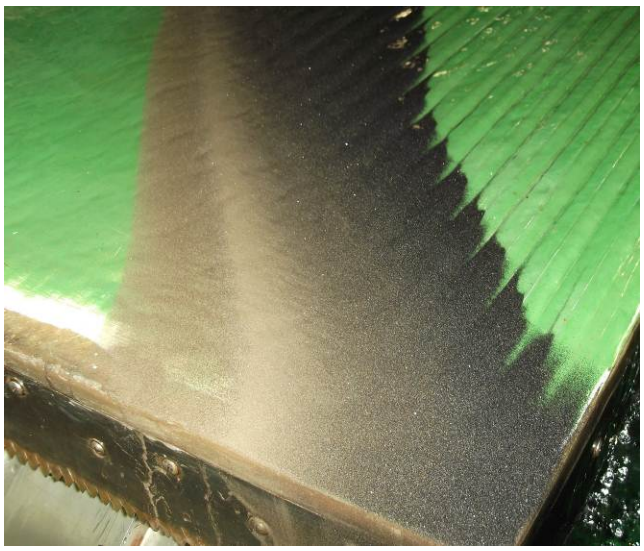

Figure 13: Cleaner Table Testwork (T3001)

With what appeared to be a relatively low level of scheelite mineral acting as a buffer between the cassiterite and iron minerals in the cleaner stage (see Figure 13 above), a third (scavenger) stage of tabling was conducted on the cleaner table middlings fraction to ensure maximum recovery of cassiterite which may have been collected in this middlings fraction. Figure 14 below shows a photo of this scavenger stage, showing that there was sufficient cassiterite in the middlings stream to warrant the scavenger stage, but also showing a less distinctive band of cassiterite than for the same Main Skarn table stream. Splitters were set to collect a high grade cassiterite concentrate.

All table fractions were dried at low temperature, weighed and small sub-samples extracted for assay.

Figure 14: Scavenger Table Testwork (T3002)

The tabulations below present the metallurgical balance for selected assays for the three stages of wet shaking table separation on #2 Skarn Rougher Spiral Concentrate material. The full assay balances are presented in Appendix 4.5.

The rougher table (Test 3000) results are summarised in Table 9 below.

The rougher table (Test 3000) results indicate:

- Effective upgrading of tin, tungsten, arsenic and sulphur heavy minerals was achieved, suggesting that these minerals were well liberated in the feed, which was to be expected given that the table feed was a gravity concentrate produced from spiral separation and most unliberated heavy minerals would not have been recovered in the spiral stage
- A concentrate was produced at a stage mass yield of 18.1% and contained:
    - 14.3% total Sn at a stage recovery of 90.7%
    - 0.41% WO_3 at a stage recovery of 80.8%
    - 5.2% As at a stage recovery of 93%
    - 10.7% S at a stage recovery of 56.3%

- While the concentrate also contained 43% Fe, the majority (55.5%) of the Fe was rejected to the tailings stream
- Some upgrading of B (vonsenite) minerals was shown into the concentrate and middlings streams, but this was not reflected by the soluble tin distributions, which showed 72.7% being rejected to tailings (essentially in line with mass distributions)
- >90% of the F minerals were rejected to the table tailings stream
- While this sample may still contain arsenide (as per the Main Skarn sample), the relatively high recovery of S to concentrate and the higher %S in the feed might suggest that this #2 Skarn sample contains a higher level of iron sulphide minerals and/or that more of these minerals have been recovered to the rougher table concentrate (compared to the Main Skarn sample)

Some calculated feed assays did not correlate well with head assays (as highlighted in Table 9 above), as per results for the Main Skarn sample (see Section 3.1.2)

The cleaner table (Test 3001) results are summarised in Table 10 below.

Table 10: Cleaner Table Testwork – Mass and Assay Balances (T3001)

Test 3001

The cleaner table (Test 3001) results indicate:

- A reasonably high grade (but <50% Sn) tin concentrate was produced at a stage mass yield of 10.7% and contained:
    - 41.5% total Sn at a stage recovery of 32.1%
    - 0.62% WO_3 at a stage recovery of 16.3%
    - 4.88% As at a stage recovery of 10.6%
    - 1.87% S at a stage recovery of 1.9%
- A significant proportion of Sn, W, Fe, S and As minerals were concentrated into the middlings fraction, supporting the decision to re-process this stream as outlined above
- Soluble Sn and B (vonsenite) minerals were mainly concentrated into the tailings stream, while being predominantly distributed into the middlings fraction with the bulk of the mass
- >90% of the F minerals were rejected to the table middlings and tailings streams

The scavenger table (Test 3002) results are summarised in Table 11 below.

Table 11: Scavenger Table Testwork – Mass and Assay Balances (T3002)

The scavenger table (Test 3002) results indicate:

- A reasonably high grade (but <50% Sn) tin concentrate was produced at a stage mass yield of 4.3% and contained:
    - 41.5% total Sn at a stage recovery of 13.6%
    - 0.94% WO_3 at a stage recovery of 8.9%
    - 5.83% As at a stage recovery of 4.4%
    - 2.83% S at a stage recovery of 1.5%
- A significant proportion of Sn, W, Fe, S and As minerals were concentrated into the tailings fraction, indicating that further recovery of liberated heavy minerals from this cleaner middlings stream is likely to be limited
- >98% of the soluble Sn and B (vonsenite) minerals were rejected to the table tailings stream
- >96% of the F minerals were rejected to the table tailings streams

The overall results from the combined rougher, cleaner and scavenger table circuit are summarised in Table 12 below. These results indicate:

- Combination of cleaner and scavenger stage concentrates would produce a reasonably high grade (but <50% Sn) tin concentrate at a table circuit stage mass yield of 2.5% and containing:
    - 41.5% total Sn at a table circuit stage recovery of 37%
    - 0.62% WO_3 at a table circuit stage recovery of 18.6%
    - 5.09% As at a table circuit stage recovery of 13.1%
    - 16.7% Fe at a table circuit stage recovery of 1.4%
    - 2.08% S at a table circuit stage recovery of 1.5%
    - 0.005% soluble Sn at a table circuit stage recovery of 0.6%
    - 0.008% B at a table circuit stage recovery of 1.5%

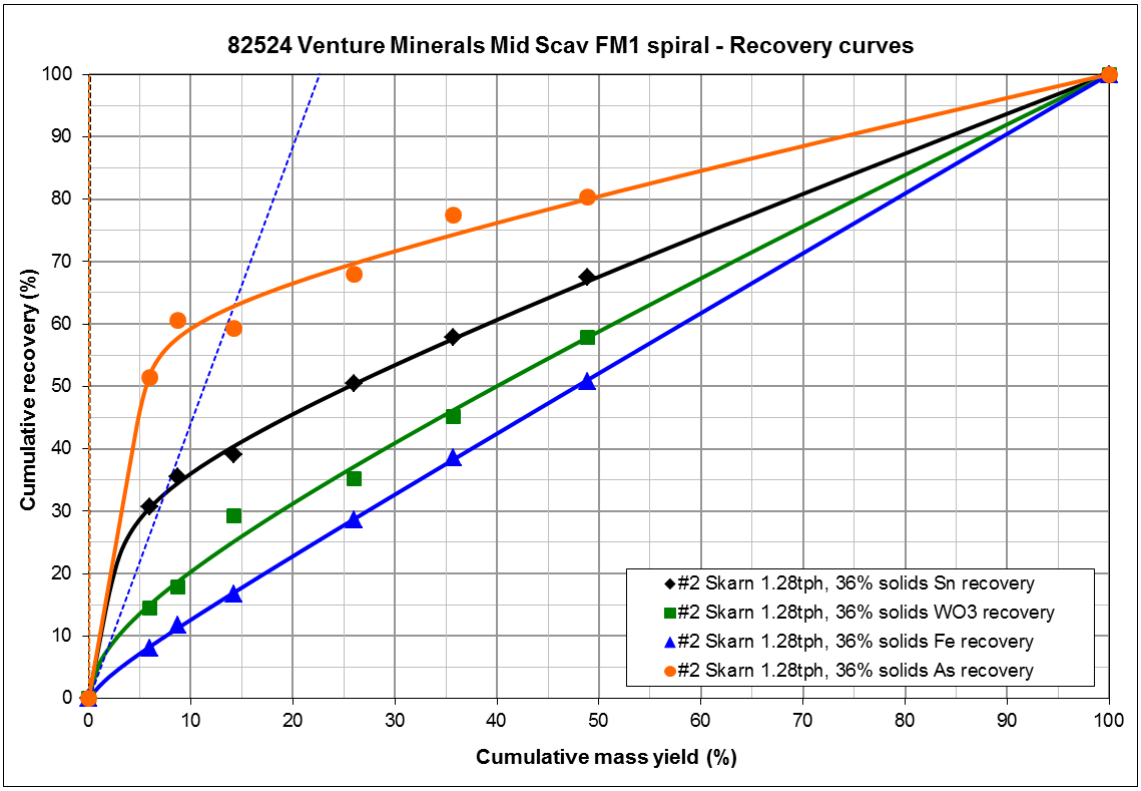
4.2.3 FM1 Spiral Separator Testwork on Rougher Spiral Middlings (T4001-3)

With the larger amount of sample available, a series of three release tests were carried out using a fine mineral spiral (FM1 – 6.5 turn version) to determine potential performance in a scavenger stage processing Chinese Rougher Spiral Middlings material.



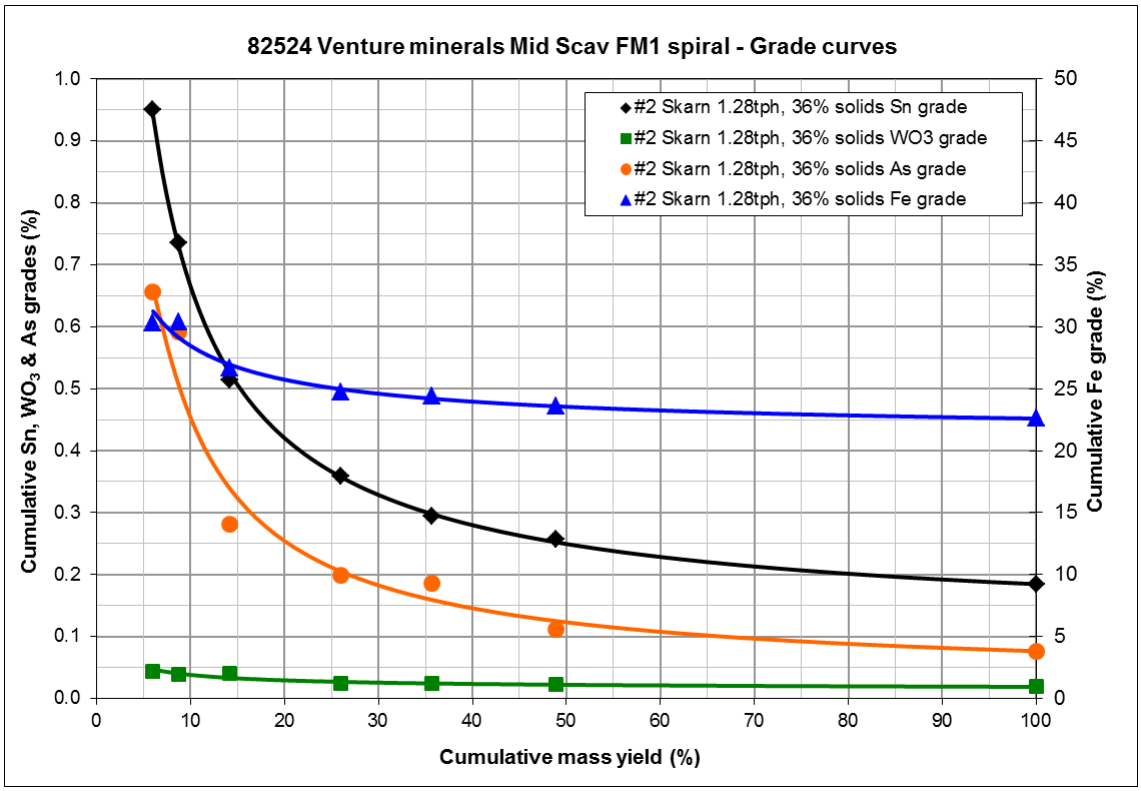
All tests were conducted at a target feed rate of approximately 1.2 t/h @ 30-35% solids. Splitters were adjusted between tests to vary the concentrate, middling and tailing mass yields. The test fractions were weighed wet, dried at low temperature (<70^{o}C) and re-weighed. Sub-samples of each test fraction were extracted for assay.

The mass flow and assay data were tabulated for each test and are presented in Appendix 4.7. Release curves for tin (Sn), tungsten (WO_3), iron (Fe), arsenic (As), soluble tin (sol Sn), boron (B) and fluorine (F) were delineated from the test data. The release curves for recovery and grade versus mass yield are presented in Figure 15 and Figure 16 below. For clarity Sn, WO_3, Fe and As curves are presented in separate charts from the soluble Sn, B and F. The release curves for separation efficiency are presented in Appendix 4.7.

The recovery and grade curves in Figure 15 and Figure 16 below and the detailed data in Appendix 4.7 show:

- Some upgrading of Sn, WO_3 and As minerals was achieved at recoveries of approximately 6% mass, 30% Sn, 15% WO_3 and 50% As, suggesting that a reasonable amount of liberated tin minerals were present in the Chinese Rougher Spiral Middlings material
- The feed contained ~0.2% Sn (~0.02% soluble Sn) and a concentrate containing approximately 1% Sn (~0.02% soluble Sn) was achieved at a concentrate mass yield of 6%
- While some upgrading of W minerals to concentrate did occur, the feed contained only ~0.02% WO_3, suggesting most of the liberated scheelite had been recovered to Chinese Rougher Spiral Concentrate
- For concentrate mass yields >5% the Sn & As recovery curve gradients reduce significantly, indicating poor separation and limited upgrading of the remaining Sn and As minerals, most likely due to them being very fine, coarse or unliberated
- The recoveries for Fe, soluble Sn and B were only marginally higher than the mass yield indicating poor response to gravity upgrading by spirals
- The F data points were very scattered and it was not possible to define a grade curve, but the data does indicate a slight downgrading of F into spiral concentrate

Given the aim of a rougher spiral mids scavenging stage such as this one would be to maximise recovery of liberated Sn minerals, while also reducing the amount of material going to downstream cleaning with wet shaking tables, a concentrate mass yield slightly greater than that at which optimum separation efficiency is achieved would like be targeted. In this case, a concentrate mass yield of ~15-20% may be targeted, which would result in recovery of ~45% Sn, ~65% As and ~30% WO_3 to a concentrate containing ~0.45% Sn, ~0.3% As and ~0.03% WO_3.



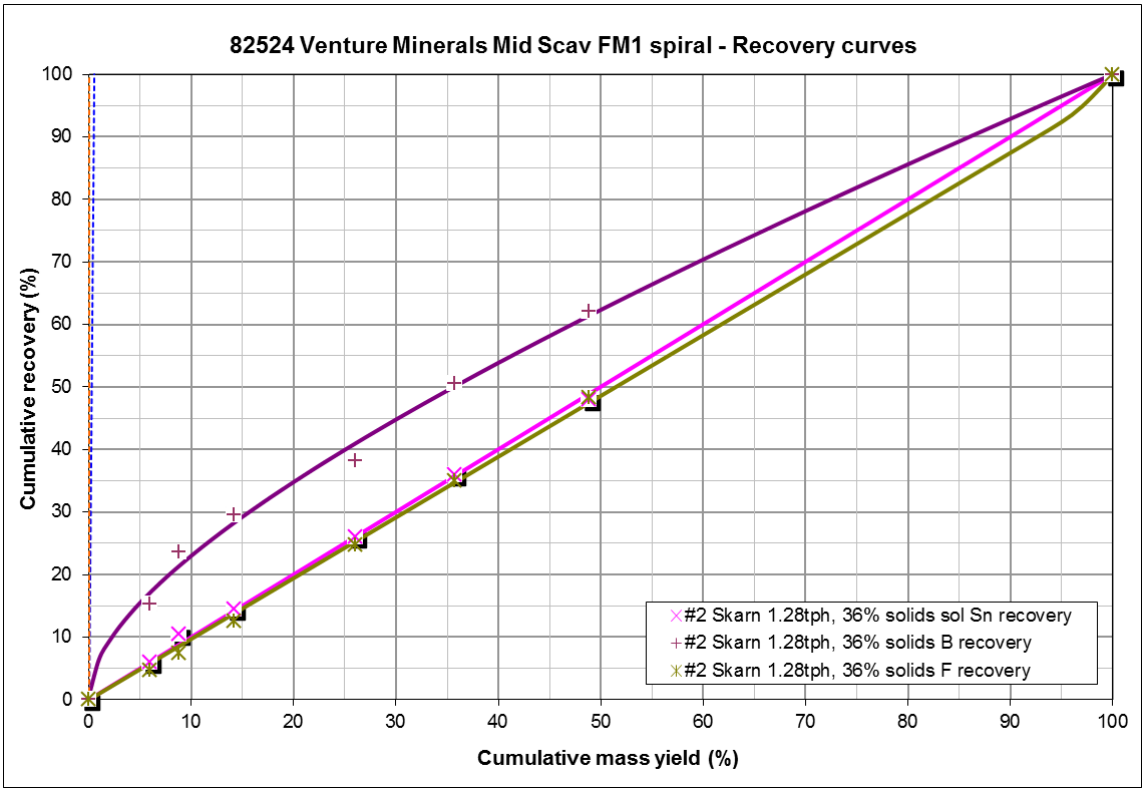


Figure 15: Scavenger Spiral Recovery & Grade Curves for Sn, WO_3, Fe & As (T4001-3)

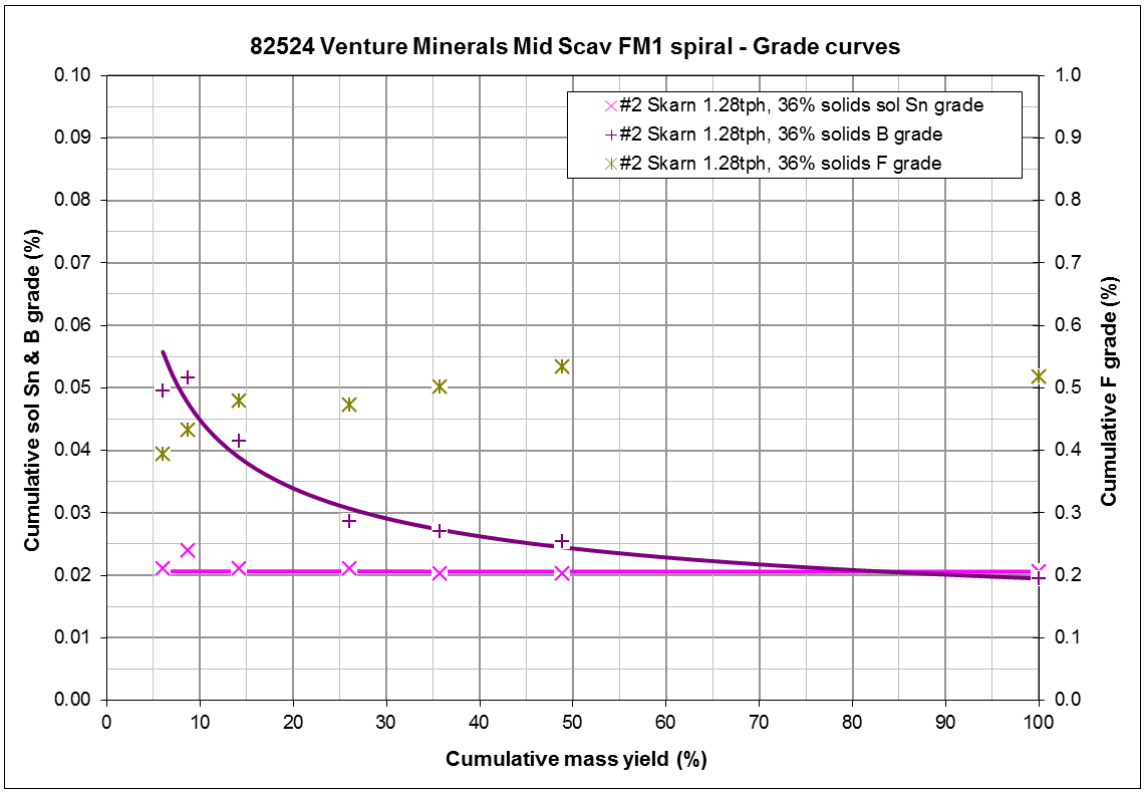

Figure 16: Scavenger Spiral Recovery & Grade Curves for soluble Sn, B & F (T4001-3)

4.2.4 Wet Shaking Table Testwork on Rougher Spiral Middlings (T4004-6)

The Rougher Spiral Middlings sample was initially processed through a rougher stage of wet shaking table separation. Figure 17 below shows a photo of the rougher stage, illustrating the lack of a distinctive band of light brown cassiterite. Nevertheless, splitters were set to collect a sufficiently large concentrate sample to ensure negligible loss of liberated Sn and W minerals, so tabling of rougher stage middlings was not considered necessary.

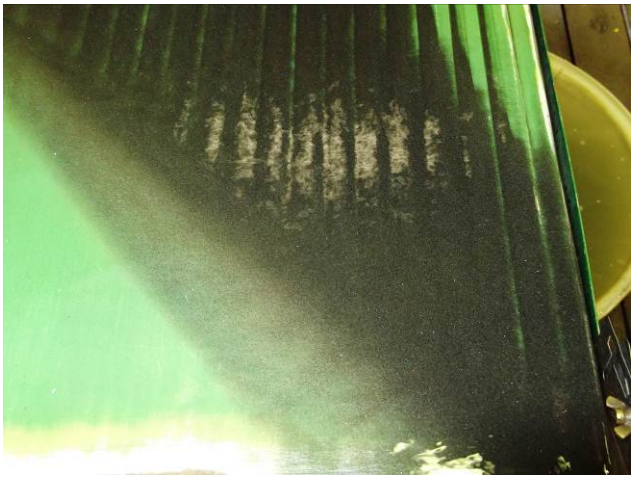

Figure 17: Rougher Table Testwork (T4004)

The rougher concentrate was then reprocessed through a cleaner stage of wet shaking table separation, in which a narrow band of Sn (cassiterite) was observed, along with a dark grey band of most likely W (scheelite) and iron minerals (see Figure 18 below). Splitters were set to collect concentrate which contained as much cassiterite as possible without cutting significantly into the scheelite / iron mineral band, in order to produce a high grade Sn concentrate.

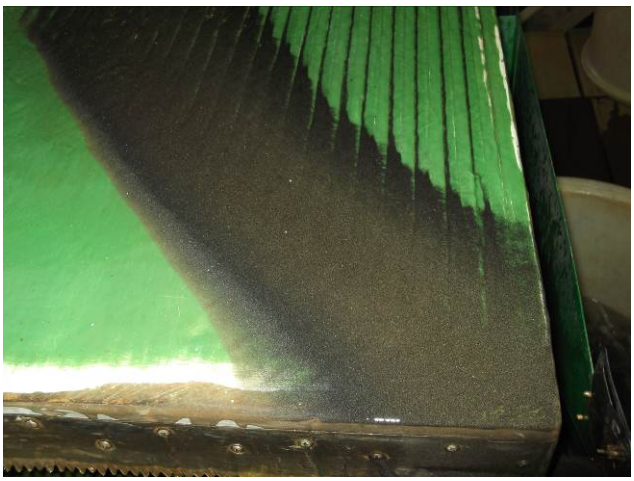

Figure 18: Cleaner Table Testwork (T4005)

With the aim being to produce a high grade tin concentrate, the third stage of tabling for this sample was run on the cleaner stage concentrate as a re-cleaner stage to determine whether more high grade concentrate could be produced from the rougher spiral middlings stream. Figure 19 below shows a photo of this re-cleaner stage, again showing a band of high grade cassiterite which splitters were set to collect.

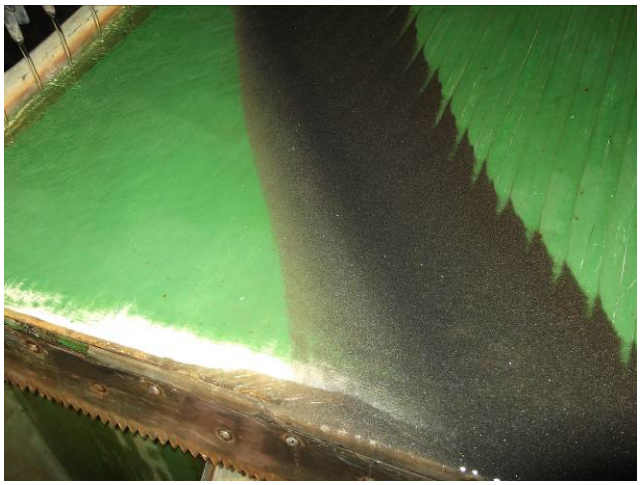

Figure 19: Re-Cleaner Table Testwork (T4006)

All table fractions were dried at low temperature, weighed and small sub-samples extracted for assay.

The tabulations below present the metallurgical balance for selected assays for the three stages of wet shaking table separation on #2 Skarn Rougher Spiral Middlings material. The full assay balances are presented in Appendix 4.8.

The rougher table (Test 4004) results are summarised in Table 13 below.

Table 13: Rougher Table Testwork – Mass and Assay Balances (T4004)

The rougher table (Test 4004) results indicate:

- Effective upgrading of tin and tungsten heavy minerals was achieved (with similar concentrate upgrade ratios to those achieved in rougher table tests on rougher spiral concentrate material), suggesting that a reasonable amount of these minerals were still liberated in the rougher spiral middlings material
- Significant upgrading of sulphur and arsenic heavy minerals was achieved (with much higher concentrate upgrade ratios than those achieved in rougher table tests on rougher spiral concentrate material), suggesting that there may be a higher proportion of heavy iron/sulphur minerals, such as pyrite and/or arsenopyrite, present in this rougher spiral middlings material
- A relatively low grade concentrate was produced at a stage mass yield of 7% and contained:
    - 1.53% total Sn at a stage recovery of 36.2%
    - 0.13% WO_3 at a stage recovery of 28.1%
    - 1.22% As at a stage recovery of 68.2%
    - 14% S at a stage recovery of 85.8%
- Some upgrading of B (vonsenite) minerals was shown into the concentrate stream, but this was not reflected by the soluble tin distributions, which showed 73.1% being rejected to tailings (essentially in line with mass distributions)
- >96% of the F minerals were rejected to the table tailings and middlings streams
- Some calculated feed assays again did not correlate well with head assays (as highlighted in Table 13 above)

The cleaner table (Test 4005) results are summarised in Table 14 below.

The cleaner table (Test 4005) results indicate:

- A still reasonably low grade tin concentrate was produced at a stage mass yield of 16.3% and contained:
    - 6.86% total Sn at a stage recovery of 66.5%
    - 0.34% WO_3 at a stage recovery of 46%
    - 4.12% As at a stage recovery of 71%
    - 8.59% S at a stage recovery of 14%
- A significant proportion of S minerals, likely to be in the form of iron sulphide minerals such as pyrite, were rejected to the middlings and tailings fractions, while As was predominantly recovered to concentrate, which might again suggest the presence of arsenide mineral
- Soluble Sn and B (vonsenite) minerals were upgraded slightly into the concentrate stream, but mainly recovered into the middlings and tailings streams
- >96% of the F minerals were rejected to table middlings and tailings streams

The re-cleaner table (Test 4006) results are summarised in Table 7 above.

The re-cleaner table (Test 4006) results indicate:

- A reasonably high grade tin concentrate was produced at a stage mass yield of 6.2% and contained:
    - 32.9% total Sn at a stage recovery of 26.8%
    - 0.93% WO_3 at a stage recovery of 18.5%
    - 6.49% As at a stage recovery of 9.2%
    - 4.77% S at a stage recovery of 3.4%
- Further rejection of soluble Sn and B (vonsenite) and F minerals was achieved, with >95% of each being rejected to tailings

The overall results from the combined rougher, cleaner and re-cleaner table circuit are shown in Appendix 4.8.

4.2.5 Overall Gravity Circuit Balances (#2 Skarn Sample)

The overall gravity circuit mass and tin balances for the #2 Skarn sample, relative to the Chinese Rougher Spiral Feed, are shown in
Figure 20 below.

The data for the Chinese Rougher Spiral stage was supplied by Venture Minerals and is attached in Appendix 4.10 for reference.

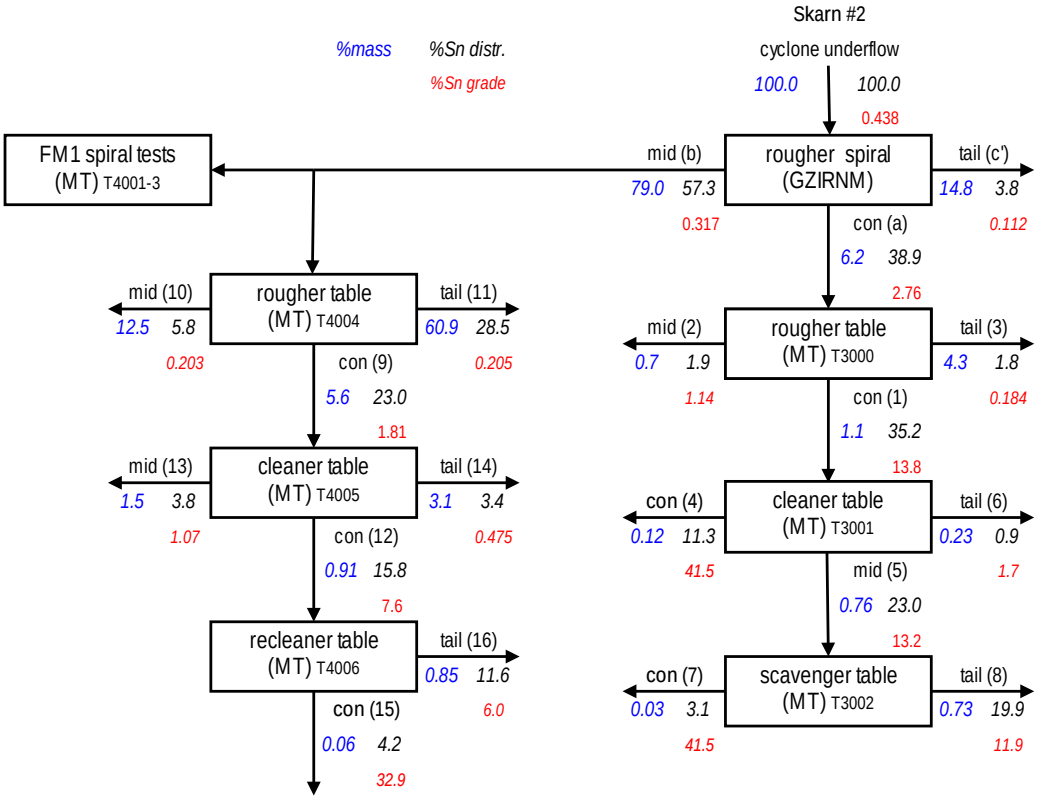

Figure 20: Overall Gravity Circuit Mass and Tin Balances – #2 Skarn Sample

The overall gravity circuit results have also been combined to illustrate cumulative mass and elemental balances relative to Chinese Rougher Spiral Feed (for Sn & WO_3) and/or Con+Mid (for all other elements). This data is presented in detail in Appendix 4.9, while Table 16 below summarises the data for key elements and Figure 21 below illustrates the cumulative gravity circuit concentrate grade (for key elements) versus cumulative Sn recovery to concentrate.

Table 16: Cumulative Mass and Elemental Balances for Gravity Circuit (#2 Skarn)

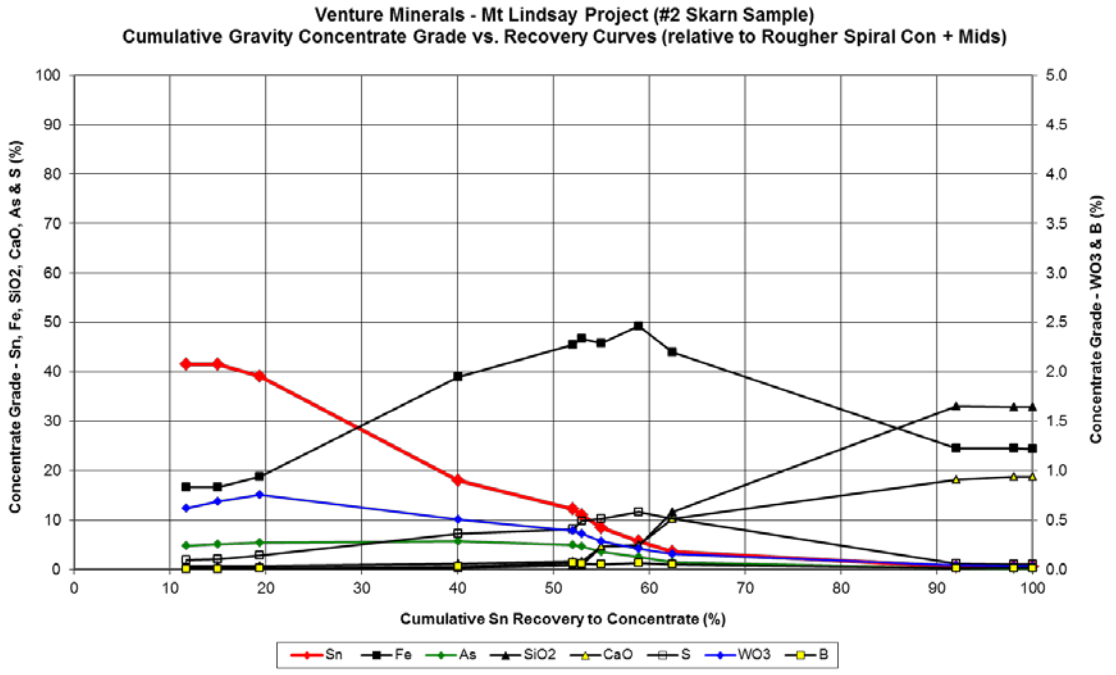

Figure 21: Cumulative Gravity Circuit Concentrate Grade vs Tin Recovery (#2 Skarn)

The data in Table 16 above and Figure 21 above show that:

- Combination of cleaner con (4), scavenger con (7) and re-cleaner con (15) would produce a relatively high grade (but <50% Sn) tin concentrate at an overall gravity circuit stage mass yield of 0.21% and containing:
    - 39.2% total Sn at a gravity circuit recovery of 18.7% (19.4%[2])
    - 0.75% WO_3 at a gravity circuit recovery 4.7% (5.2%[2])
    - 5.47% As at a gravity circuit recovery 7.8%[2]
    - 18.7% Fe at a gravity circuit recovery 0.2%[2]
    - 2.81% S at a gravity circuit recovery 0.7%[2]
    - 0.009% soluble Sn at a gravity circuit recovery 0.1%[2]
    - 0.017% B at a gravity circuit recovery 0.4%[2]
- As recovery of tin to gravity concentrate increases (past approximately 25%), the concentrate Sn, WO_3 and As grades decrease steadily, while the Fe and S grades steadily increase, suggesting that additional tin in the lower grade gravity circuit streams has either been misplaced (not captured into the high grade concentrate streams) or is not fully liberated
- The increase in recovery of Fe, S and B to concentrate is consistent with the lower specific gravity (than cassiterite, scheelite and arsenide minerals) iron and sulphide and vonsenite minerals being rejected to table circuit middlings streams
- The main contaminant in the lower grade gravity circuit streams appears to be Fe, S and As, so depending on what mineralogical form these minerals are present in, it may be possible to increase recovery of Sn by including these streams in the gravity circuit concentrate and subjecting them to flotation to remove the sulphide (possibly arsenopyrite) minerals
    - Removal of these Fe/S minerals from spiral circuit concentrates, prior to cleaning on wet shaking tables, may have some benefit in that these minerals would not compete for a place in the table circuit concentrate and Sn recoveries may improve
    - However, feedback from Venture Minerals suggests that their preferred approach may be to allow the sulphide minerals to build up in the gravity circuit and then remove them using flotation

[2] Relative to Chinese Rougher Spiral concentrate + middlings

4.3 CONCEPTUAL FLOWSHEET

Based on the results from test work covered in this report, Venture Minerals proposed the process flowsheet in Figure 22 below.

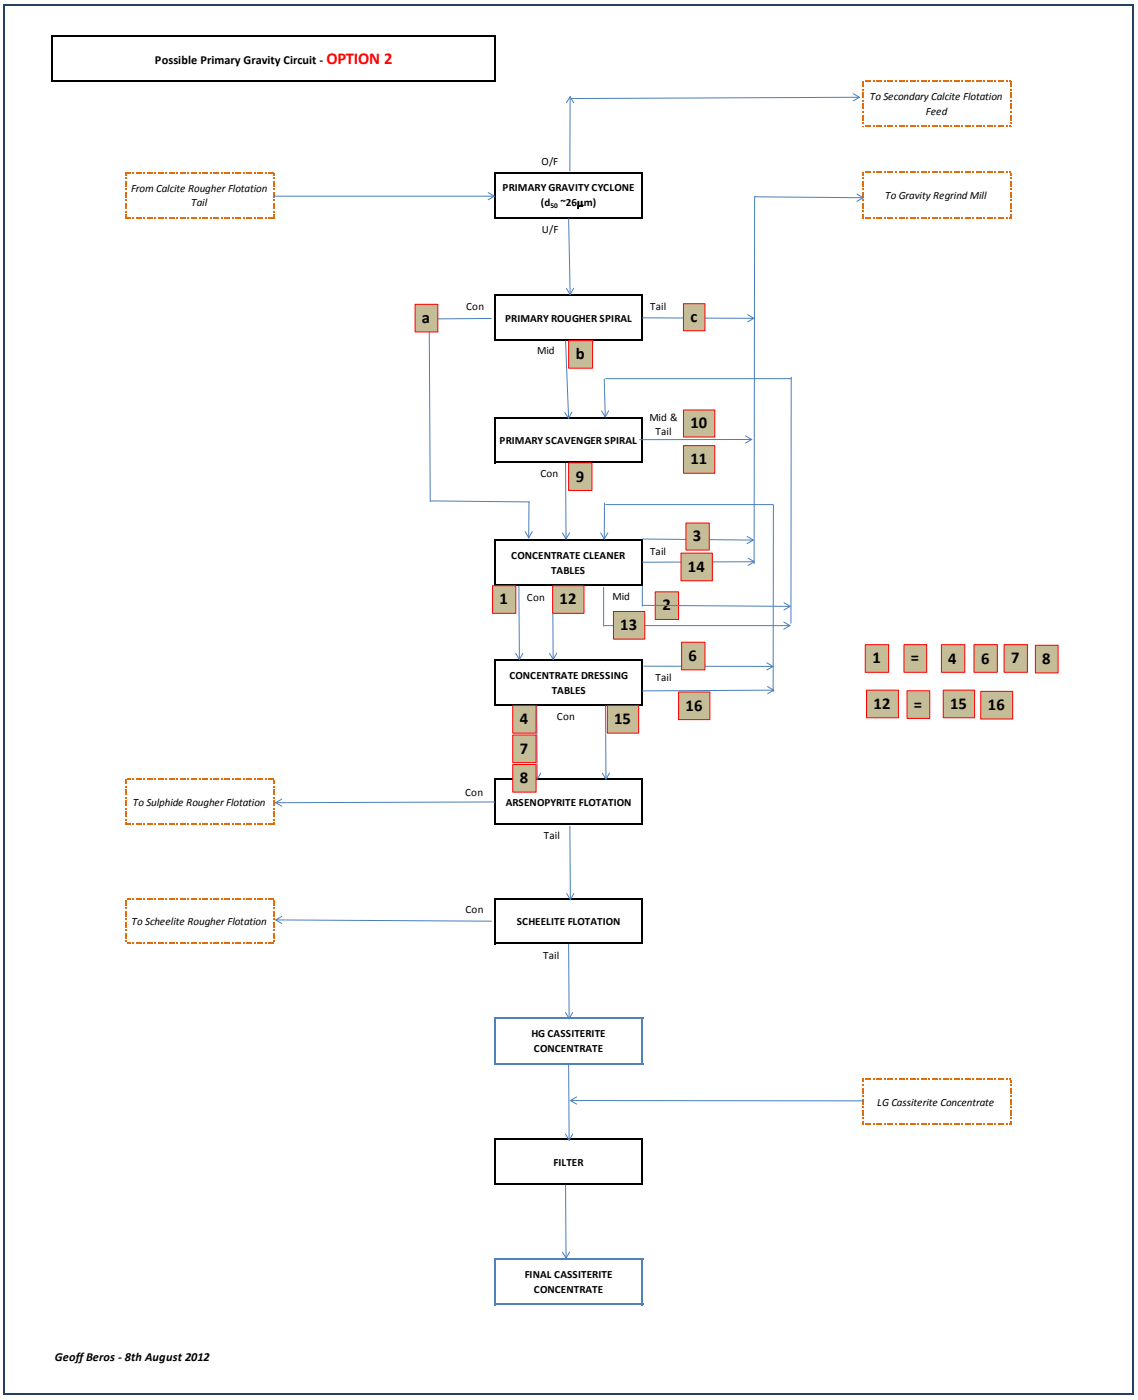

Figure 22: Proposed Conceptual Flowsheet – Client

With respect to the gravity stages of the process flowsheet, the conceptual process flowsheet in Figure 23 below illustrates the approach which Mineral Technologies would recommend.

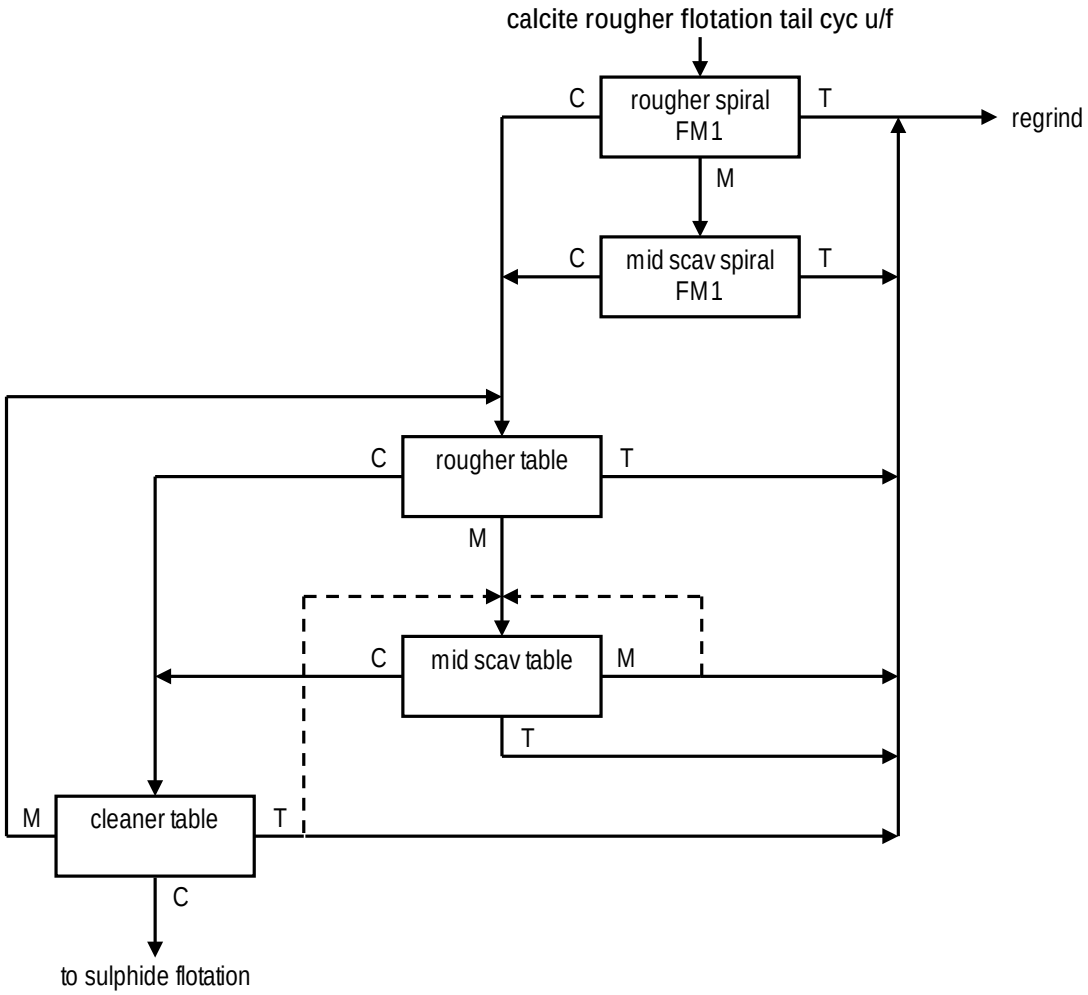

Figure 23: Proposed Conceptual Flowsheet – Mineral Technologies

A key aspect of the conceptual process flowsheet in Figure 23 above is the minimisation of recirculating streams in the wet table circuit. This approach is recommended for a number of reasons, including:

- The benefit of recirculating streams is to recover misplaced valuables (as opposed to unliberated / composite minerals)
- Wet tables are relatively high efficiency separators and, by definition, the quantity of misplaced valuables is likely to be quite low
- There is significant potential for recirculated material to build up and not escape the circuit, resulting in overloading and reduced separation efficiency

- The concept of recirculating table streams to spirals is not recommended for two reasons:
    - Tables are higher efficiency separators than spirals, so recirculating a mid or tailing stream from tables to spirals is not likely to result in metallurgical benefit
    - Spiral and table circuits are no longer separate circuits, which can be an issue with operation and performance measurement
- Tailings from the gravity circuit are not reject streams and will report to a regrind mill, so there are no direct losses from the circuit
- The one stream that may be suitable for recirculation is the middling from the cleaner stage table, as the aim of this stage of separation is to produce a relatively high grade concentrate, so some Sn/WO_3 will be necessarily sent to middling
- Two other table circuit streams are shown reporting to regrind but with an option of recirculating to earlier stages
    - The preferred option would be to regrind these streams unless further characterisation confirms that these streams contain misplaced material (i.e. valuables that were contained in these streams not due to liberation and/or particle size issues)

Venture Minerals requested that modelling / prediction of the potential impact of recirculating selected gravity streams on total Sn recovery and grade be conducted. However, it was concluded that there would be little benefit from attempting this for several reasons, including:

- The testwork was conducted using laboratory-scale wet shaking tables that would certainly provide a more efficient performance than production units
    - This was done due to the small feed mass available
    - Many of the fractions were so small that it was not even possible to operate the table at a specific feed rate
    - In effect the testwork should be regarded as analytical only
- As discussed above, recirculation of streams around high efficiency separators such as wet shaking tables should be kept to a minimum
- The nature / characteristics of the valuable minerals in streams designated for regrind and/or recirculation are not yet understood and it is therefore not possible to estimate the recovery from recirculation of these streams, i.e. there is no data available to indicate the reasons for valuable minerals reporting to middlings and tailings

4.4 FINAL GRAVITY PRODUCTS

The following (highest Sn grade) end products were sent to Venture Minerals for further processing, including sulphide and scheelite flotation:

- Main Skarn Sample
    - Stream 4 (spiral con cleaner table con T1001) – 205.3g
    - Stream 7 (spiral con scav table con T1002) – 116.8g
    - Stream 15 (spiral mid re-cleaner table con T2007) – 29.4g
    - Stream 8 (spiral con scav table tail T1002) – 520g
- #2 Skarn Sample
    - Stream 4 (spiral con cleaner table con T3001) – 93.3g
    - Stream 7 (spiral con scav table con T3002) – 20.3g
    - Stream 15 (spiral mid re-cleaner table con T4006) – 11.5g
    - Stream 8 (spiral con scav table tail T3002) 567.7g

The following (highest Sn grade) end products were sent to Venture Minerals for further processing, including sulphide and scheelite flotation:

Note: The full reserve amounts (as per above masses) of these samples were sent to Venture Minerals.

In order to better understand the characteristics of potential recycle / regrind streams, small sub-samples of all other streams from both Skarn samples (except for Stream 11 – spiral mid rougher table tails[3]) were also sent to Venture Minerals for microscopic evaluation.

With this information in hand, the conceptual gravity process flowsheet could be reviewed in terms of potential recirculation of streams which may contain misplaced tin minerals. The scope of work for test work on the proposed larger sample should also then include stages to test the reprocessing of these streams, following two full stages of spiral separation (rougher and mids scavenger) and three stages of tabling (rougher, mids scavenger and cleaner) using the largest wet shaking table possible (based on available mass) for each stage to provide a better indication of likely performance at full-scale.

The larger product streams should also allow sufficient sample to extract sub-samples for further characterisation work, including assay by size & density, mineralogy, etc., which will provide further indications as to the amenability of each stream to further gravity separation / recirculation. Larger concentrate samples will also be available for downstream processing stages, including sulphide and scheelite flotation.

[3] Stream 11 samples are very large and are almost certainly would go to gravity tailings for regrinding, so it was decided that the additional work required to split these streams down was not warranted.

5. APPENDICES

5.1 SCOPE OF WORK

A Sample Receipt & Preparation

1 Receive (as dewatered slurry nom 85-90% solids) the following fractions produced from testwork in China from individual skarn samples:
Main Skarn (MacDonald Zone)
i) Spiral Concentrate (con 1) - 16.5kg
ii) Spiral Middlings (con 1,2) - 9.2kg
iii) Spiral Middlings (mid 1,2) - 44.2kg (in 2 bags)
#2 Skarn (Radford Zone)
i) Spiral Concentrate (con 1) - .6.5kg
ii) Spiral Middlings (con 1,2) - 5.8kg
iii) Spiral Middlings (mid 1,2) - 27.4kg (in 2 bags)

2 Separately combine and homogenise for each skarn the two spiral middling fractions (con1,2 & mid 1,2). Extract sub-sample (2kg) for assay / reference

3 Separately homogenise the spiral concentrates for each separate skarn and extract sub-samples for assay / reference (250g)

B Wet Table Testwork on Spiral Concentrates

1 Conduct wet table testwork on the separate spiral cons. It is expected that two stages of table separation (rougher & cleaner) will be required

2 Dry and weigh the table fractions. Extract sub-samples for assay (with minimum mass extracted from smallest streams)

C FM1 Spiral Release Testwork on Spiral Concentrates*

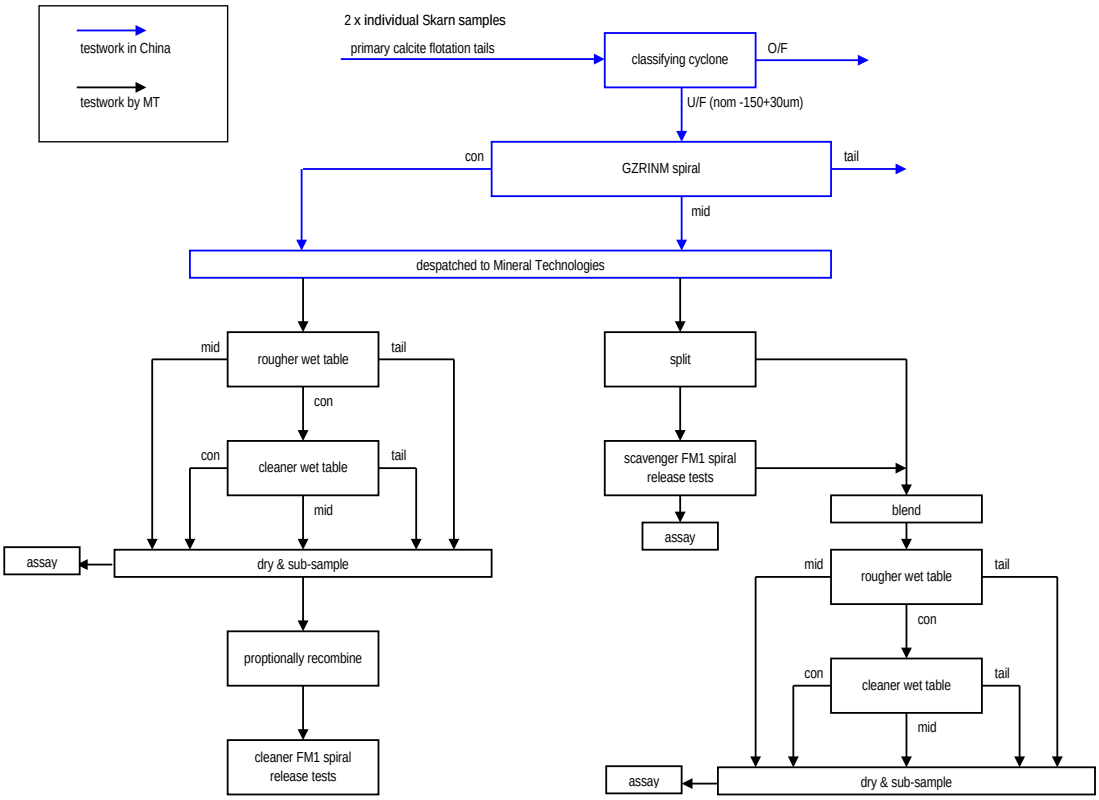
D FM1 Spiral Release Testwork on Spiral Middlings

1 Conduct a series of release tests on each separate skarn middlings using FM1 spiral at 1.0-1.2 t/h @ 30-35% solids

2 Dry and sub-sample the test fractions and submit for assay

3 Prepare release curves for Sn, WO3 & up to 2 other selected elements recovery & grade vs mass yield

E Wet Table Testwork on Spiral Middlings



1 Using reserve from spiral testwork, conduct wet table testwork on the middlings from each skarn. It is expected that two stages of table separation (rougher & cleaner) will be required

2 Dry and weigh the table fractions. Extract sub-samples for assay

F Reporting & Management

1 Prepare technical report including:
i) description of testwork equipment and procedure
ii) tabulated stage spiral and wet table mass and assay data
iii) stage spiral and table performance curves for WO3/Sn grade and recovery versus mass yield
iv) overall mass and assay balance for testwork flowsheet
vi) discussion of results, conclusions & recommendations

The testwork flow diagram is shown below:

Note: Part C was to include FM1 spiral release tests on proportionally reconstituted residual / reserve concentrate materials from Part B, but due to a lack of available mass, and after consultation with Venture Minerals, this work was not conducted.

REVISED ANALYTICAL REPORT

This is a Revised Analytical Report and as such replaces and supersedes our previous Analytical Report 7096 dated 5 October 2012. Please destroy all copies of the report 7096. The results (to 95%, 2σ, confidence level) for Radium-226, Radium-228, Thorium-228 & Lead-210 of one (1) solid sample, as received at our laboratory on 27 September 2012, is detailed on page two of this report.

Reported values for total Uranium (U-234 + U-235 + U-238) and total Thorium (Th-232) are calculated from Certificate of Analysis provided by the client.

MDL:	Radium-226	0.03 Bq/g	Radium-228	0.03 Bq/g
	Thorium-228	0.03 Bq/g	Lead-210	0.03 Bq/g

Method: LTP No. 4(a) Gamma Spectrometry Analysis

EXECUTIVE SUMMARY

Batch and pilot scale magnetic separation, gravity separation, and froth flotation testwork has been conducted on a variety of ore samples, and rougher magnetic separation products from Venture Minerals Ltd's, Mt Lindsay project.

Salient results are presented in the following tables and figure:

Head Assays – MacDonald Main Composite and Radford No. 2 Skarn Ore Samples

Sample ID	Al_2O_3 (%)	As (%)	CaO (%)	Cu (%)	Cr (%)	Fe (%)	S (%)	SiO_2 (%)	Sn (ppm)	WO_3 (%)
MacDonald	8.08	0.79	7.40	0.65	0.02	40.6	23.6	14.9	617	0.05
Radford	11.3	4.07	10.06	0.78	0.01	32.7	15.8	19.5	521	0.20

Head Assay – DTR/DTW Composite

CONCLUSION AND RECOMMENDATIONS

Batch flotation tests were conducted on various ore samples, and magnetic product streams to develop a process for reducing sulphur levels to target values. The target total sulphur in magnetite concentrates was <0.5 %, and this level was achieved in 4 of the 6 tests conducted on the DTR/DTW composite sample. None of the flotation tests conducted on the MacDonald and Radford magnetite concentrate samples achieved the target sulphur level, possibly due to oxidation of the pyrrhotite species in these products.

One of the objectives of the pilot plant operations was to assess whether freshly ground and beneficiated ore would alleviate the pyrrhotite oxidation, and produce a magnetite product with a sulphur grade lower than 0.5 %. This level was not achieved during the pilot plant operations, however subsequent re-processing of the magnetite concentrate, with excess additions of potassium amyl xanthate and sulphuric acid did produce a low sulphur (0.06%) magnetite concentrate stream.

Due to the complexity of the proposed process flowsheet, continuous operation of the whole process was not able to be conducted. The pilot plant processing was split (decoupled) into 4 separate operations:

- Stage 1A – Comminution of the bulk ore sample to P_{80} of 120 µm, rougher magnetic separation, pyrrhotite flotation on the rougher magnetics, re-grind of the pyrrhotite flotation tailings to P_{80} of 40 µm, cleaner magnetic separation, and pyrrhotite flotation of the cleaner magnetic concentrate.
- Stage 1B – Rougher copper flotation of the Stage 1A rougher non-magnetics, and bulk sulphide flotation on the combined copper rougher tailings and cleaner non-magnetics from Stage 1A.
- Stage 2 – Calcite rougher and cleaner flotation of the Stage 1B sulphide flotation tailings, followed by scheelite rougher and cleaner flotation of the calcite flotation concentrates. The calcite flotation rougher tailings were cyclone de-slimed, and subjected to gravity beneficiation using a combination of spirals and multiple stages of wet tabling to recover a scheelite gravity concentrate.
- Stage 3 – Various product streams from the Stage 2 operations (cyclone overflows, and gravity middlings and tailings) were combined, and re-ground to P_{80} of 45 µm. The re-ground material was subjected to 2 stages of de-sliming, and acidic conditioning with sodium silicofluoride, followed by multiple stages of rougher, scavenger, cleaner and re-cleaner flotation to produce a tin concentrate.

In general terms, the pilot plant operated satisfactorily. Some materials handling issues were experienced on the first day of operation (Stage 1A), mostly associated with settling of milled solids in various slurry transfer lines. A re-configuration of the pumping systems, involving smaller diameter discharge lines, and re-routing of these lines to ensure that vertical transfers overcame materials handling issues.

The other main issues experienced through the piloting operations were related to the small sample mass processed, and the subsequent small mass flow to various stages : scheelite gravity and flotation, and tin flotation. The Client and the Client's Representatives particularly wanted to assess the effects of recirculating various middlings and cleaner tailings streams within the scheelite gravity and flotation operations, and the tin flotation operations. Owing to the low mass of sample reporting to these stages, continuous operations, and closed circuit operations were not possible. An attempt at recirculating wet table middlings was made during the scheelite gravity testwork (Stage 2), however the operations ultimately had to be conducted in batches rather than continuously. Similarly, both the scheelite and tin flotation cleaning stages were conducted in batches rather than in continuous operation.

The tin flotation did not produce acceptable grades or recovery to the concentrate streams. This is may have been partially caused by changes of pH prior to the flotation arising from de-sliming before and after SSF acidification. Additional water had to be added to the cyclone underflow to achieve the required slurry density, and this addition raised the pH above the batch testwork levels.

If continuous operations of the scheelite and tin circuits need to be conducted, a significantly larger mass of sample must be processed. Approximately 15 tonnes of feed to the magnetic separation stage should generate sufficient non-magnetics to test the scheelite flotation, and tin flotation stages in continuous mode, at a practical feed rate.

Consideration should be also be given to reprocessing the tin flotation scavenger tailings to achieve higher tin recovery, at an acceptable grade.

1. INTRODUCTION

SGS Lakefield Oretest Pty Ltd (SGS) was requested by Mr. Geoff Beros, of Venture Minerals Limited (the Client) to conduct metallurgical testwork on samples from the Mount Lindsay project in Tasmania. In addition, two Clients Representatives, Mr Tony Choo, and Mr Zhang, directed sections of testwork program, specifically tin flotation, and scheelite flotation respectively.

Two testwork programs were conducted; one program consisting entirely of batch testwork, and the second program consisting of batch and continuous pilot scale testwork.

1.1 Batch Testwork Program Overview (SGS #10920)

The batch testwork program included:

- Sample preparation and assays.
- Magnetic separation.
- Batch "Sulphide" and pyrrhotite flotation testwork.
- Cyclone de-sliming.
- Spiral gravity separation.
- Wilfley wet table gravity separation.
- Falcon centrifugal gravity concentration.
- Batch flotation for both scheelite and tin processes.
- Mineralogy.

1.2 Pilot Testwork Program Overview (SGS #0098MP)

The pilot testwork program included:

- Sample preparation and assays.
- Set-up, commissioning and operation of a multi stage pilot plant.
- Off-line batch testwork on the scheelite and tin flotation processes, as directed by the Client, and the Client's Representatives.

2. SAMPLES RECEIVED

SGS received the following samples for batch testwork:

- 6 x 20 L buckets with a combined mass of 90 kg, on December 8th 2011
- 32 x 20 L buckets with a combined mass of 692 kg, on February 8th 2012
- 72 x 20 L buckets & 3 x 205 L drums with a combined total mass of 1769 kg, on April 19th 2012.
- A 205 L Drum with a mass of 315 kg.

SGS also received the following samples for the bulk piloting composite:

- A pallet of samples in bags, with a combined mass of 343 kg, on February 22nd 2012.
- 2 pallets of samples in bags, with a combined mass of 1,313 kg.

Figure 2-1 shows the as received samples. Figure 2-3 illustrates samples in the process of composite formation.

Figure 2-1 : As Received Samples

Figure 2-2: Composite Formation

Approximately 50 kg of the composite 'DTR/DTW' was provided by the Client in 1kg charges amongst the 205 L drums that arrived on April 19th 2012.

A detailed list of the McDonald and Radford samples used for the batch testwork is given in Appendix A.

A detailed list of the samples received for piloting testwork and their SGS designated sample numbers is also given in Appendix A.

3. SAMPLE PREPARATION

The pilot plant composite was prepared to nominally <4 mm using SGS's continuous crushing plant, which comprises jaw, cone and rolls crushers as illustrated in Figure 3-1:

Figure 3-1 : SGS's Continuous Crushing Plant

4. ANALYTICAL PROCEDURES USED

Most sample assays were performed at SGS Minerals, Newburn using X-ray fluorescence spectroscopy (XRF), where the sample is fused with 12/22 flux to form a glass fusion bead. The bead is then presented to the XRF machine for analysis.

Samples were also assayed at SGS' in-house analytical facility using the following techniques:

- Metals in solids: 4 acid digest, followed by inductively coupled plasma mass spectrometry, or optical emission spectrometry (ICP-MS/OES).
- S in solids: ELTRA total combustion furnace.
- True Density: Gas pycnometer.

5. HEAD ASSAYS

Head assays for the MacDonald, Radford and 'DTR/DTW' samples that were used in the batch testwork are given in Table 5-1 and Table 5-2 overleaf:

Table 5-1: Head Assays – MacDonald Main Composite and Radford No. 2 Skarn Ore Samples

Sample ID	Al (%)	As (%)	Ca (%)	Cu (%)	Cr (%)	Fe (%)	S (%)	SiO_2 (%)	Sn (ppm)	W (ppm)
MacDonald	2.14	0.79	3.37	0.65	0.02	40.6	23.6	14.9	617	390
Radford	2.99	4.07	4.58	0.78	0.01	32.7	15.8	19.5	521	1550

Table 5-2: Head Assay – DTR/DTW Composite

Sample ID	Al_2O_3 (%)	As (%)	CaO (%)	Cu (%)	Fe (%)	MgO (%)	S (%)	SiO_2 (%)	Sn (ppm)	W (%)	LOI (%)
DTR/DTW	6.77	0.15	8.91	0.07	31.2	2.98	3.97	25.0	809	0.10	1.65

Two representative sub-samples of the bulk ore sample were submitted for duplicate chemical analysis. These head assay results are given in Table 5-3:

Table 5-3 : Piloting Composite Sample XRF Head Assay

Sample ID	Al_2O_3 (%)	As (%)	CaO (%)	Cu (%)	Fe (%)	MgO (%)	S (%)	SiO_2 (%)	Sn (%)	WO_3 (%)	LOI (%)

Bulk Ore (RPT)	6.78	0.35	8.93	0.10	32.0	2.65	4.11	25.4	0.26	0.22	4.23
Bulk Ore (AVG)	**6.80**	**0.35**	**8.93**	**0.10**	**32.0**	**2.66**	**4.07**	**25.4**	**0.26**	**0.22**	**4.14**

6. TESTWORK PROCEDURES AND RESULTS

6.1 Batch Testwork

6.1.1 Sulphide (Pyrite) Cleaning

SGS received moist concentrate from sulphide flotation testwork that was conducted by a third party on the RMS non-magetics. A number of sulphide cleaner flotation tests were conducted to determine how many additional cleaner flotation stages were required to achieve maximum sulphide rejection, and increase iron units to the cleaner tailings. Flotation test conditions and results are summarised in Table 6-1 to Table 6-3 overleaf:

Table 6-1 : Sighter Flotation Test Condtions

Test #	Cleaning Stages	Conditioning Time	Flotation Time	Reagent Addition		
				PAX (g/t)	W22 (g/t)	$CuSO_4$ (g/t)
1	1	4	9	5	90	50
2	1	4	9	5	60	50
3	2	5.5	12	5	60	50
4	2	5.5	12	5	50	50

Detailed batch flotation test data are given in Appendix B.

6.1.2 Low Intensity Magnetic Separation

Low intensity magnetic separation (LIMS) was performed at a grind size of P_{80} ~ 40 µm. Samples were received at SGS as a ground slurry. The slurry was initially processed through the Ereiz L8 wet drum at 600 gauss field strength. The non-magnetics were re-passed at increasing magnetic intensity to assess the recovery effects. The gauss settings were as follows:

- Stage 1: 600 G.
- Stage 2: 900 G.
- Stage 3: 1,000 G.

Summarised LIMS cleaner/scavenger test results are given in Table 6-4 overleaf:

Table 6-4 : Sighter LIMS Test Results

Sample ID	Stream	Mass (%)	Fe		S		Sn		WO_3	
			%	% Dist'n	%	% Dist'n	%	% Dist'n	%	% Dist'n
Mac.	600 G Mags	81.1	63.4	88.9	6.32	83.2	0.03	68.3	0.01	34.4
	900 G Mags	4.6	53.6	4.2	6.52	4.8	0.05	5.6	0.04	6.8
	1,000 G Mags	1.5	40.7	1.1	6.34	1.6	0.06	2.5	0.08	4.5
	1,000 G Non-Mags	12.8	26.2	5.8	5.00	10.4	0.07	23.6	0.10	54.3
Rad.	600 G Mags	83.7	65.1	90.9	3.88	83.5	0.03	68.2	0.04	36.8
	900 G Mags	6.9	46.9	5.4	4.28	7.6	0.05	10.1	0.18	16.9
	1,000 G Mags	1.2	26.3	0.5	3.51	1.1	0.07	2.6	0.29	5.0
	1,000 G Non-Mags	8.2	23.5	3.2	3.68	7.8	0.08	19.2	0.37	41.4

LIMS scavenger separation realised increasing iron recovery to magnetic concentrate with increasing field intensity. However, there is a concomitant decrease in the iron grade of the magnetic concentrate

Detailed LIMS test data are given in Appendix B.

6.1.3 Pyrrhotite Flotation on LIMS Cleaner/Scavenger Magnetics

A number of flotation tests were performed on the MacDonald and Radford cleaner magnetic concentrate. Sub-samples of the concentrate from Section 6.1.2 above were combined on a weighted distribution basis to form the feed for the flotation tests. Flotation test conditions and results are summarized in Table 6-5 to Table 6-8 overleaf:

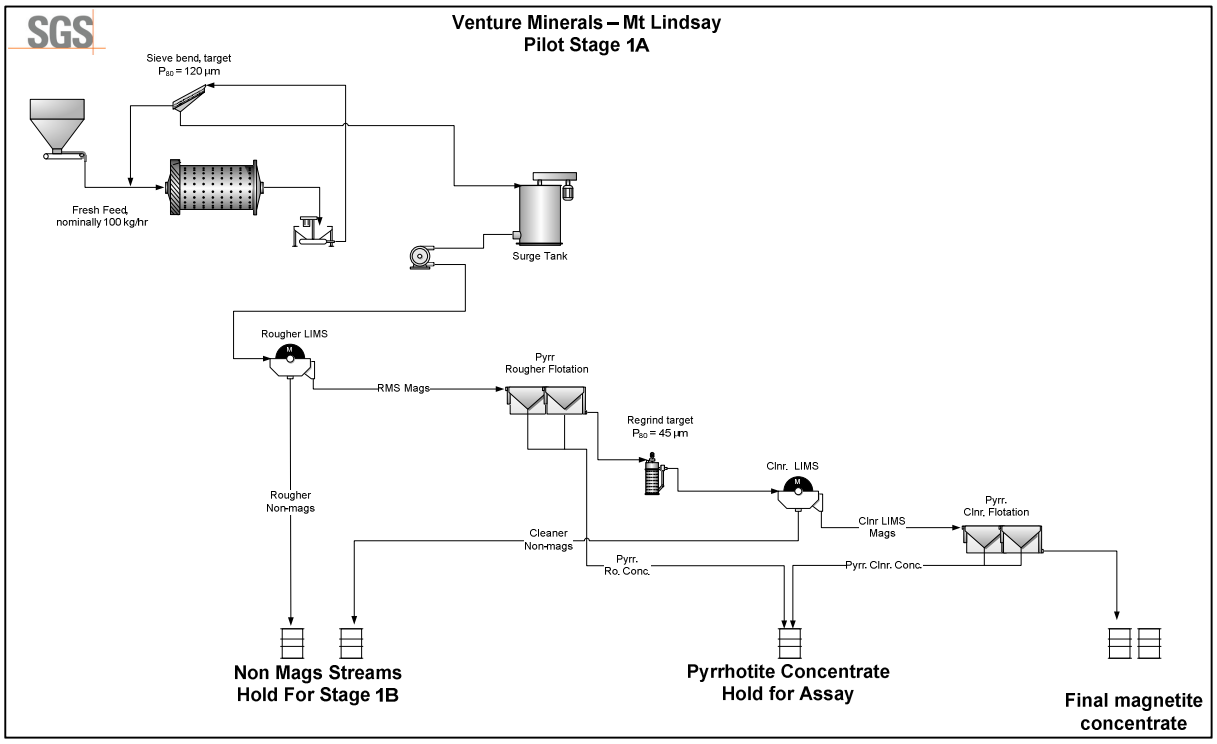
JH 192	Comb Conc	23.1	23.4	91.7
	Ro. Tails	76.9	0.64	8.3

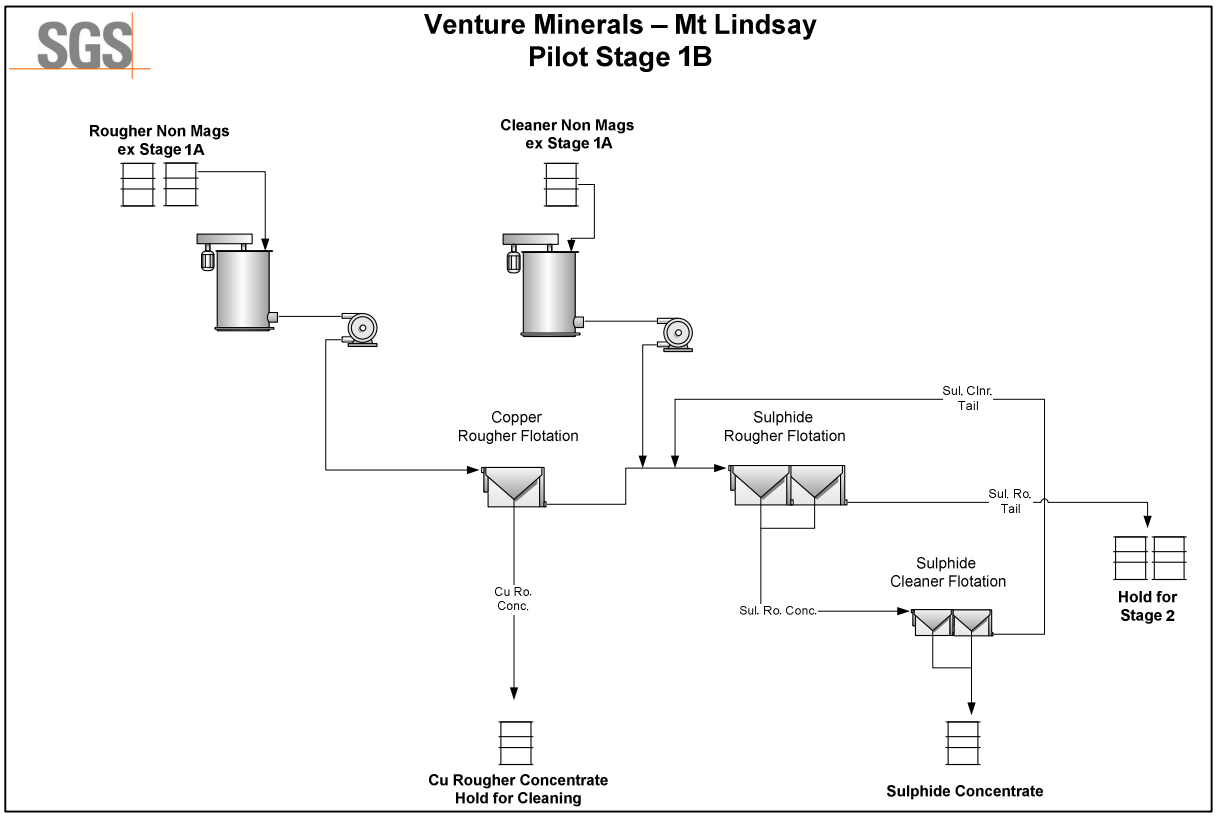
The batch pyrrhotite flotation test results indicate the following:



- Flotation tailings sulphur grades were the lowest in Test 5 for both MacDonald and Radford tests.
- The test conditions of Mac 5 and Rad 5 were reproduced in test JH156 conducted on the DTR/DTW sample. These test conditions realised the lowest tailings sulphur grade for the DTR/DTW sample also.

Detailed results, reagent additions, conditioning and flotation times for the batch flotation testwork are presented in Appendix B.**Error! Reference source not found.**

6.2 Pilot Scale Testwork - Stage 1A and Stage 1B



In consultation with the Client, it was agreed to split the Pilot Scale Testwork Stage 1 into 2 sections (Stage 1A and Stage 1B), which are illustrated in Figure 6-1 and Figure 6-2 overleaf. Flotation of the magnetic and non-magnetic streams was performed separately to enable better control of the pulp densities (% solids w/w) entering the flotation cells.

Figure 6-1: Stage 1A Flowsheet

The rougher LIMS was performed with an ERIEZ L8 laboratory wet drum magnet. The magnetics stream reported to a series of 3 conditioning tanks prior to pyrrhotite flotation (roughing) which was performed in a bank of 4 Agitair (40 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply). The pyrrhotite flotation rougher tailings were re-ground in an overflow ball mill before reporting to the cleaner LIMS (SALA WS 201 laboratory wet drum separator). The cleaner LIMS magnetics reported to a series of 3 conditioning tanks prior to pyrrhotite flotation (scavenging) which was performed in a bank of 4 Outotec (50 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply).

Figure 6-2: Stage 1B Flowsheet

The rougher LIMS non-magnetics from Stage 1A were collected into 2 x 1,500 L tanks where they were allowed to settle before decanting to ~40% solids (w/w). The tanks were agitated and the slurry, along with dilution water was pumped into a series of 3 conditioning tanks prior to rougher copper flotation, in a bank of 2 Outotec (10 L capacity/cell) mechanically agitated flotation machines (fitted with an external air supply). The rougher concentrate was collected for additional batch scale cleaning testwork conducted by others. The rougher tailings stream reported to 3 conditioning tanks prior to pyrite rougher flotation in a bank of 4 Outotec (50 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply). The pyrite rougher concentrate reported to a cleaning stage consisting of 3 conditioning tanks and flotation in a bank of 4 Outotec (10 L capacity/cell) mechanically agitated flotation machines (fitted with an external air supply).

6.2.1 Grinding Circuit

The crushed ore (~ 4 mm) was initially fed at the rate of ~150 kg/h to a urethane lined rod mill (500 mm internal diameter and 1,500 mm effective grinding length (EGL)). The rod mill discharge slurry (~60% solids w/w) was pumped by a Sala SPV 181 vertical spindle slurry pump to a DSM screen (static sieve bend with 279 µm slots). The screen oversize gravitated back to the rod mill feed and the screen undersize slurry reported to a 500 L mechanically agitated surge tank. The slurry was diluted in the surge tank to ~35 % solids (w/w) and pumped with a peristaltic hose pump to the rougher LIMS. After ~4 hours of operation, the mill feed rate was reduced to ~120 kg/h, and further reduced to ~100 kg/h 2 hours after that for the remainder of the pilot plant Stage 1A operation.

The regrinding of the pyrrhotite rougher tailings was performed in a rubber lined Hardinge conical ball mill charged with ~90 kg of 25 mm and 35 mm diameter high chrome steel balls. The ball mill

discharge was pumped by a Sala SPV 181 vertical spindle slurry pump to a DSM screen (static sieve bend with 100 µm slots) The screen oversize gravitated back to the ball mill feed and the screen undersize slurry reported to the cleaner LIMS.

6.2.2 Flotation Conditions

The general conditions, and reagent additions for the pilot plant were as follows:

- Target grind of P_{80} = 120 µm.
- Feed rate of ~150kg/h, initially reduced in consultation with the client to ~120 kg/h, and further reduced to ~100 kg/h.
- The flotation feed was pumped to baffled, overflow conditioning tanks operating in series. Each tank was agitated by an IKA overhead electric stirrer, fitted with a stainless steel, 90 mm diameter Rushton turbine impellor. The impellors were operated at ~290 RPM. Conditioning was performed at ambient temperature.

The estimated flotation cell residence times are given in Table 6-11:

Table 6-11 : Stage 1 Flotation Cell Residence Times

Unit Operation	Rel' Mass to Conc. (%)	Flotation Time (mins)	Flotation % Solids (w/w)	Cell Vol. (L) Req'd	Cell Selection (Effective Vol. L)	# of Cells	Adj'd # of Cells
Pyrrhotite Rougher	10	30	30	104	34.0	3.1	4
Pyrrhotite Scavenger	10	30	30	94	42.5	2.2	3
Cu Rougher	16	2	30	13	6.8	1.9	2
Pyrite Rougher	33	30	30	192	42.5	4.5	5
Pyrite Cleaner	25	10	20	34	34.0	1.0	2

The target reagent additions and conditioning times are detailed in Table 6-12 overleaf:

Table 6-12 : Pilot Stage 1 Flotation Reagent Scheme

Stream	Reagent	Target Dose (g/t)	Add'n Point	Conditioning Time (mins)
Pyrrhotite Rougher	$CuSO_4$	250	Pyrrh Ro Cond. 1	5

6.2.3 Low Intensity Magnetic Separation

The rougher LIMS was performed using a ERIEZ L8 laboratory wet drum magnetic separator, operating in counter-current mode, which is most effective for maximum recovery of the magnetic concentrate. The feed pulp was agitated prior to being fed into the separator with sufficient water flow to keep the level weir slightly overflowing at all times. The unit was operated at 900 gauss field intensity at the drum surface.

The cleaner LIMS was performed using a SALA WS 201 laboratory wet drum magnetic separator, which consists of a permanent magnet, mounted on an adjustable yoke, that is completely enclosed in a non-magnetic, stainless steel drum. The magnetic field strength is approximately 1,200 gauss at the drum surface.

6.2.4 Steady State Survey and JKSimMet Mass Balance

A "steady state" survey was conducted by sampling all relevant plant streams when "steady state" operation was achieved. For Stage 1A, a full stream slurry sample was taken every - 20 minutes over a period of 70 minutes. The mass balancing module of JKSimMet V5.1 was used to calculate the "steady state" mass balance summarised in Table 6-13 overleaf:

Table 6-13 : Pilot Flotation - JK Steady State Mass Balance for Stage 1A

Stream	Port	Solids (kg/h) Exp.	Solids (kg/h) Bal.	Fe Assay % Exp.	Fe Assay % Bal.	S Assay % Exp.	S Assay % Bal.

6.2.5 Final Magnetite Concentrate Reprocessing

A sub-sample of the final magnetite concentrate underwent additional flotation processing to investigate whether the sulphur content could be reduced to the Client's target level (<0.5%). The slurry pH was adjusted with sulphuric acid, and excess PAX was added to the flotation pulp. A bank of 4 Agitair (8 L capacity/cell), mechanically agitated flotation machine, fitted with an external air supply, was used. Summarised test conditions and results are given in Table 6-14 and Table 6-15**Error! Reference source not found.**:

Table 6-14: Final Magnetite Cleaning Flotation Test Conditions

Stream	Reagent Addition (g/t)

Detailed pilot flotation results, including grinding circuit and flotation circuit logsheets, flotation feed sizing data, mass balance data and survey assays for Pilot Scale Testwork Stage 1A and Stage 1B are presented in Appendix C.

6.3 Pilot Scale Testwork - Stage 2

The sulphide (pyrite) flotation tailings from the Stage 1A and Stage 1B testing progressed to the pilot scale Stage 2 testwork. The Stage 2 pilot plant flowsheet is illustrated in Figure 6-3 overleaf.

The primary gravity concentration was conducted using a CPG FM1 spiral. The middlings stream from the primary rougher spiralling was re-passed over the FM1 spiral as a scavenging step. The spiral concentrates were blended, and divided into four batches and then processed by a Holman-Wilfley wet table.

Figure 6-3: Stage 2 Flowsheet

6.3.1 Primary Calcite Rougher, Scavenger and Cleaner 1 Flotation

The calcite rougher, scavenger and cleaner 1 flotation stages were conducted in continuous operation, and the cleaner 2 flotation was conducted in 2 batch operations.

The rougher and scavenger 1 flotation was performed in a bank of 4 Outotec (50 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply) after 3 stages of conditioning. The scavenger 2 flotation was performed in a bank of 2 Agitair (40 L capacity/cell) mechanically agitated flotation machines (fitted with an external air supply). The combined concentrates from the rougher and scavenger flotation reported to cleaner flotation (bank of 4 Outotec 10 L capacity/cell, mechanically agitated flotation machines, fitted with an external air supply). The cleaner 1 concentrate was collected and subsequently cleaned in 2 batches using the same bank of 4 Outotec cells (10 L capacity/cell).

The general conditions, and reagent additions for the primary calcite flotation were as follows:

- Feed rate of ~150kg/h.
- The flotation feed was pumped to baffled, overflow conditioning tanks operating in series. Each tank was agitated by an IKA overhead electric stirrer, fitted with a stainless steel, 90 mm diameter Rushton turbine impellor. The impellors were operated at ~290 RPM. Conditioning was performed at ambient temperature.

The estimated flotation cell residence times are given in Table 6-16:

Table 6-16 : Primary Calcite Flotation Cell Residence Times

Unit Operation	Rel' Mass to Conc. (%)	Flotation Time (mins)	Flotation % Solids (w/w)	Cell Vol. (L) Req'd	Cell Selection (Effective Vol. L)	# of Cells	Adj'd # of Cells
Rougher	15.0	10	35	55	42.5	1.3	2
Scav 1	5.0	10	32	52	42.5	1.2	2
Scav 2	5.0	10	30	54	34	1.6	2
Clnr 1	20.0	10	15	30	8.5	3.6	4

The target reagent additions and conditioning times are detailed in Table 6-17:

Table 6-17 : Primary Calcite Flotation Reagent Scheme

Stream	Reagent	Target Dose (g/t)	Add'n Point	Conditioning Time (mins)
Rougher/Scav1	Na_2CO_3	1,000	Cond. Tank1	5
	$NaSiO_3$	2,500	Cond. Tank 2	7
	GYWA	300 & 160	Cond. Tank 3 & Cell 3	5
	W22	As req'd	Feed Launder	-
Scav 2	GYWA	80	Feed Launder	-
	W22	60	Feed Launder	-
Clnr 1	GYWA	200	Feed Launder	-

6.3.2 Primary Calcite Batch Cleaner 2 Flotation

The concentrate from calcite cleaner 1 flotation was subjected to a second stage of cleaning. The flotation was performed in a bank of 4 Agitair (40 L capacity/cell), mechanically agitated flotation machine (fitted with an external air supply). The cleaner 2 flotation was conducted in 2 batches at a target pulp density of 20% solids (w/w). The test conditions are summarised in Table 6-18:

Table 6-18 : Calcite Cleaner 2 Flotation Conditions

Batch No.	Na_2SiO_3 (g/t)	Conditioning Time (min)	Frothing Time (min.)
1	50	5	30
2	100	5	65

6.3.3 Scheelite Flotation

The combined concentrates from the primary calcite cleaner 2 flotation were conditioned at elevated temperature prior to scheelite flotation. The hot conditioning was conducted at a pulp density 53% solids (w/w), and at a temperature of 90°C, for 90 minutes. The following reagents were added to the hot conditioning:

- GYWA (200 g/t).
- NaOH (4,000g/t).
- Na_2SiO_3 (100 kg/t).

After 90 minutes of conditioning, the concentrate was allowed to cool, before transferring it to a bank of 4 Outotec (10 L capacity/cell) flotation machines. The scheelite rougher flotation continued for 30 minutes, without further reagent addition.

The scheelite rougher concentrate was highly dispersed due to the Na_2SiO_3, addition, and could not be effectively settled or thickened. Under instruction from the Client, a process for detwatering the rougher concentrate by flotation was developed. This was conducted in a number batches using a Denver 5 L bench flotation cell. The concentrates generated from the dewatering process were combined to form the scheelite cleaner stage 1 flotation feed. The tailings were collected in a bucket, and subsequently combined with the scheelite cleaner 1 tailings.

The flotation conditions and cells use for the 3 scheelite cleaner flotation stages are presented in Table 6-19:

Table 6-19 : Scheelite Cleaner Flotation Conditions

Flotation Stage	Float Cell	GYWA (g/t)	NaHS (g/t)	Frothing Time (min.)
Cleaning 1	Agitair 4x8 L	100	-	17
Cleaning 2	Denver 2.5 L	-	22	5
Cleaning 3	Denver 1.5 L	-	-	4

6.3.4 Primary Calcite Flotation Tailings Deslime

The scavenger 2 flotation tailings from Section 6.3.1 above, were diluted to approximately 15% solids (w/w) with Perth tap water, and deslimed using a 50 mm Mozley hydrocyclone fitted with a 11 mm vortex finder and 8 mm spigot. The cyclone overflow (COF) slurry was stored in 1,000 L iso-containers prior to decanting, and proceeding to Pilot Scale Testwork Stage 3, whilst the cyclone underflow (CUF) was stored 1,000 L iso-containers prior to transfer to an agitated tank for feed to the gravity separation process.

A number of COF and CUF stream samples were taken during the desliming operations. The survey samples were filtered, dried and weighed, and submitted for chemical analysis. Summarised results are given in Table 6-20 to Table 6-22 overleaf:

Table 6-20 : Calcite Deslime Survey 4 Assay Results

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3

6.3.5 Spiral Testwork

The CUF from Section 6.3.4 above was diluted with Perth tap water to ~30 % solids (w/w) and fed to a CPG FM1 spiral at a feedrate of ~2.5 t/h. Three streams were collected; the concentrate which was in a 1,000 L iso-container, the middlings which were collected into a 2,000 L agitated tank, and the tailings which were collected into several 1,000 L iso-containers. The middlings were diluted to 30 - 35 % solds (w/w) and re-processed over the FM 1 spiral at a feedrate of ~2.2 t/h. The concentrate and tailingings streams were collected from the scavenger spiral, and combined with the respective concentrates and tailings rougher spiraling stage.

The spiral separation stage is illustrated in Figure 6-4 and **Error! Reference source not found.** overleaf:

Figure 6-4 – Spiral Plant General View and Operation

"Steady state" full stream sample surveys of all relevant streams were conducted during the rougher spiralling, and scavenger spiralling operations by full stream sampling of all relevant streams. For the rougher spiralling test, 5 timed samples were taken every 5 minutes over a period of 20 minutes. For the scavenger spiralling test, 2 samples were taken over a 5 minute period.

Summarised spiral survey results are given in Table 6-23 and Table 6-24:

Table 6-23 : Rougher Spiral Survey Results

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3
Concentrate	34.9	22.2	0.91	0.66
Middlings	30.5	19.2	0.17	0.06
Tailings	34.6	19.9	0.22	0.10

Table 6-24 : Scavenger Spiral Survey Results

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3
Concentrate	76.4	19.4	0.19	0.07
Tailings	23.6	18.7	0.14	0.05

The rougher spiral concentrates and scavenger spiral concentrates were combined for further gravity concentration using the Holman-Wilfley wet table.

6.3.6 Holman-Wilfley Table Testwork

The combined concentrates from the spiral operations were split into 4 batches and processed over the Holman-Wilfley 2000 wet table. The wet tabling was conducted in batches to allow recycling of the middlings and tailings streams from the first and following batches to the feed for subsequent batches.

The Holman-Wilfley wet table is illustrated in Figure 6-5:

Figure 6-5 : Holman-Wilfley Table Separation

The rougher table middlings were collected and re-passed over the table in a scavenging step. The rougher table tailings were recombined with the scavenger table middlings and tailings streams. The rougher table concentrates and the scavenger table concentrates were combined and re-passed over the table in a cleaner step. The cleaner concentrates were collected for batch flotation testing, whilst the cleaner middlings and tailings streams were collected and recycled over the table with the next batch of sample for rougher tabling. The procedure was repeated until all 4 batches were processed.

Slurry survey samples were taken from the concentrate, middlings and tailings streams over a period of 10, 5 & 10 seconds respectively, to allow the Holman-Wilfley table performance to be assessed. Wet table survey results are summarised in tables Table 6-25 to Table 6-27:

Table 6-25 : Rougher Wet Tabling Survey Results

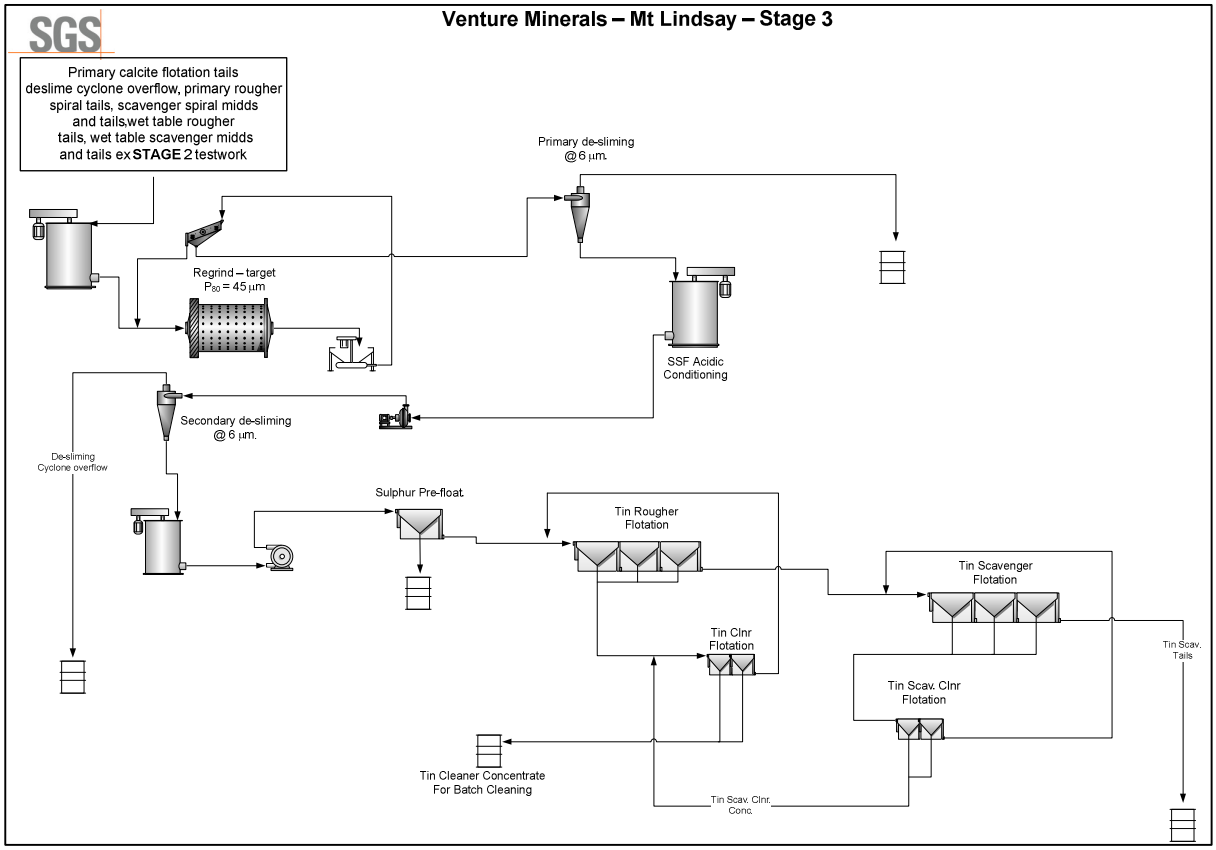
6.3.7 Gravity Concentrate - Arsenopyrite and Scheelite Flotation

The cleaner wet table concentrates from Section 6.3.6 above were combined and a sub-sample extracted for assay. Perth tap water was added to the combined concentrates to form a slurry of 35% solids (w/w). The combined concentrate slurry was transferred to a baffled tank which was agitated by an IKA overhead electric stirrer, fitted with a stainless steel, 90 mm diameter Rushton turbine impellor. The impellor was operated at ~300 RPM. Sulphuric acid was added to the slurry to maintain a slurry pH of ~2, over a 10 minute period. The acidic pre-treatment was performed at ambient temperature.

The slurry was then filtered, washed and divided into 3 batches prior to batch flotation in a 3.8 litre flotation cell. The flotation conditions are summarised in Table 6-28:

Table 6-28 : Arsenopyrite and Scheelite Flotation Test Reagent Additions



Batch Number	Reagent Additions (g/t)					
	Arsenopyrite Flotation			Scheelite Flotation		
	$CuSO_4$	PAX	W22	Na_2SiO_3	GYWA	W22
1	115	160	12	500	350	3
2	115	160	7.2	500	350	3
3	115	160	27	500	350	9

Detailed test results, including grinding circuit and flotation circuit logsheets, flotation feed sizing data, mass balance data and survey assays for Pilot Scale Testwork Stage 2 are presented in Appendix D.

6.4 Pilot Scale Testwork - Stage 3

Various flotation tailings and gravity test middlings and tailings from Pilot Scale Testwork - Stage 2 progressed to Pilot Scale Testwork – Stage 3. The Stage 3 pilot plant flowsheet is illustrated in Figure 6-3:

Figure 6-6: Pilot Scale Testwork - Stage 3 Flowsheet

6.4.1 Re-grinding Circuit

Testwork products from Pilot Plant Testwork - Stage 2 were combined in an agitated tank, prior to re-grinding. The feed slurry was fed to a rubber lined overflow ball mill (Quinn 16” x 16”, charged with ~ 50kg of 25 mm and 35 mm diameter high chrome steel balls) at an initial rate of ~60 kg/hr. The ball mill discharge slurry (~60% solids w/w) was pumped by a Sala SPV 181 vertical spindle slurry pump to a DSM screen (static sieve bend with 100 µm slots). The screen oversize gravitated back to the ball mill feed and the screen undersize slurry reported to a 2,500 L mechanically agitated tank. After a period of operation, a large circulating load built up, and the mill feed rate was reduced to ~30 kg/hr. The following testwork products from Pilot Plant Testwork - Stage 2 were combined prior to re-grinding:

- Rougher spiral tailings.
- Scavenger spiral tailings.
- Rougher wet table tailings.

- Scavenger wet table middlings.
- Scavenger wet table tailings.

6.4.2 Re-grind Product De-sliming

The primary calcite COF (ex Pilot Scale Testwork – Stage 2) was added to the re-grind product and blended (by re-circulation, and cross pumping) between a 2,500 L mechanically agitated tank and a 2,000 L mechanically agitated tank, Following blending, the slurry was diluted to approximately 15 % solids (w/w) with Perth tap water. The diluted slurry was de-slimed using a 50 mm Mozley cyclone fitted with a 8mm vortex finder and 4.5 mm spigot. The COF slurry was stored in 1,000 L iso-containers, prior to being decanted and combined in a single 1,000 L iso-container. The CUF was collected in a 500 L agitated tank in preparation for the acidic sodium silicofluoride (SSF) conditioning stage.

A number of COF and CUF stream samples were taken during the de-sliming operations. The survey samples were filtered, dried and weighed, and submitted for chemical analysis to give an indication of the cyclone performance. Summarised results are given in Table 6-29 to Table 6-32:

Table 6-29 : Re-grind De-sliming - Survey 19 Assay Results

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3
Overflow	23.3	21.2	0.13	0.10

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3
Overflow	27.4	21.3	0.13	0.11
Underflow	72.6	19.8	0.18	0.07

6.4.3 SSF Acidic Conditioning

The cyclone underflow from Section 6.4.2 above was agitated in a 500 L mixing tank. Sodium silicofluoride was added at a rate of 1,000 g/t, and sulphuric acid was added to maintain the pH at ~3 for 20 minutes. Approximately 5,250 g/t of sulphuric acid was added to the SSF acidic conditioning process.

6.4.4 Post SSF De-sliming

After completion of the SSF acidic conditioning in Section 6.4.3 above, the slurry was blended (by re-circulation, and cross pumping) between a 2,500 L mechanically agitated tank and a 2,000 L mechanically agitated tank and diluted to approximately 15 % solids (w/w) with Perth tap water. The diluted slurry was de-slimed using a 50 mm Mozley cyclone fitted with a 8 mm vortex finder and 4.5 mm spigot as before. The COF slurry was stored in 1,000 L iso-containers prior being decanted and filtered. The CUF was transferred to a 1,500 L mixing tank in preparation for continuous tin flotation.

A number of COF and CUF stream samples were taken during the post SSF de-sliming operations. The survey samples were filtered, dried and weighed, and submitted for chemical analysis to give an indication of the cyclone performance. Summarised results are given in Table 6-33 and Table 6-34:

Table 6-33 : Post SSF De-sliming - Survey 23 Assay Results

Fraction	Mass %	Solids Assay %		
		Fe	Sn	WO_3
Overflow	2.1	22.1	0.14	0.10

		Fe	Sn	WO_3
Overflow	2.6	22.0	0.14	0.10
Underflow	97.4	19.9	0.19	0.08

6.4.5 Tin Flotation

Following the re-grind, and SSF acidic conditioning and dual de-sliming, the CUF stream reported to the tin flotation process. A sulphide pre-float was conducted prior to tin flotation, and this was conducted in a bank of 4 Agitair (8 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply). The sulphide pre-flotation tailings reported to tin rougher flotation which was conducted in a bank of 4 Outotec (50 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply). Prior to tin rougher flotation, the pulp was conditioned through a series of 2 conditioning tanks. The tin rougher tailings underwent scavenger flotation, which was also conducted in a bank of 4 Outotec (50 L capacity/cell), mechanically agitated flotation machines (fitted with an external air supply). The tin scavenger tailings were collected, thickened and filtered.

The tin rougher concentrate was cleaned in a bank of 4 Outotec (10 L capacity/cell) mechanically agitated flotation machines (fitted with an external air supply). The cleaner tailings were re-cycled to the head of the rougher flotation cells. The tin cleaner concentrate was collected and filtered.

The tin scavenger concentrate was cleaned in a bank of 4 Agitair (8 L capacity/cell) mechanically agitated flotation machines (fitted with an external air supply). The scavenger/cleaner tailings were re-cycled to the head of the scavenger flotation cells. The scavenger concentrate was re-cycled to the head of the cleaner cells.

The general conditions, and reagent additions for the tin flotation process were as follows:

- Feed rate of ~60kg/h.
- The flotation feed was pumped to baffled, overflow conditioning tanks operating in series. Each tank was agitated by an IKA overhead electric stirrer, fitted with a stainless steel, 90 mm diameter Rushton turbine impellor. The impellors were operated at ~300 RPM. Conditioning was performed at ambient temperature.

The estimated flotation cell residence times are summarised in Table 6-35:

Table 6-35 : Tin Flotation Cell Residence Times

Unit Operation	Rel' Mass to Conc. (%)	Flotation Time (mins)	Flotation % Solids (w/w)	Cell Vol. (L) Req'd	Cell Selection (Effective Vol. L)	# of Cells	Adj'd # of Cells
Sulphide Preflot	1.0	15	35	33	6.8	4.8	5

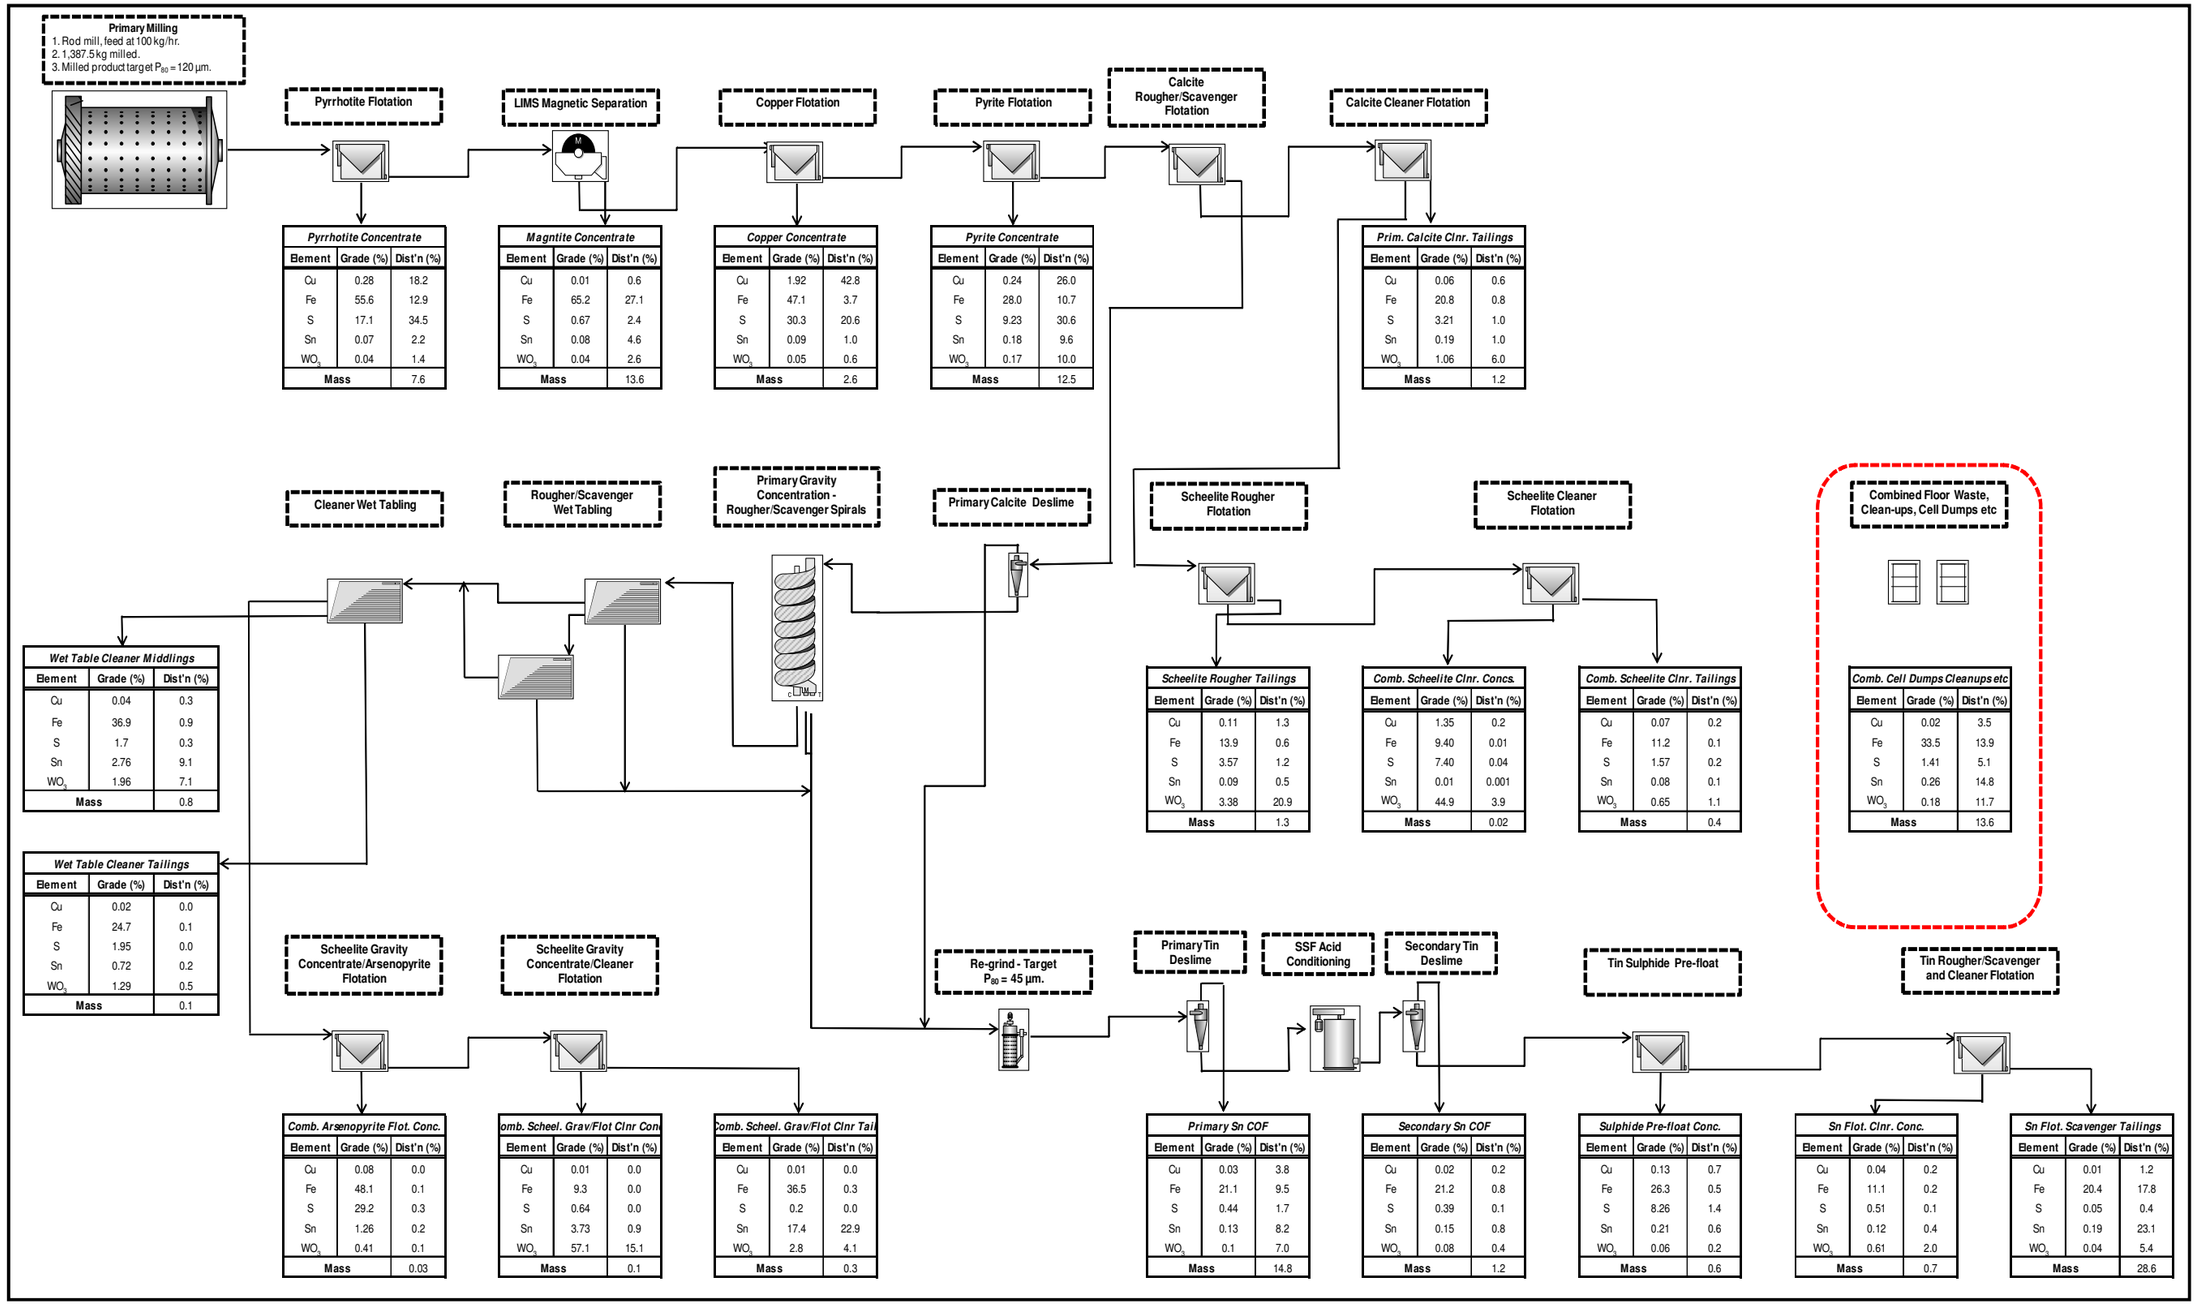
Detailed Pilot Scale Testwork – Stage 3 results, including grinding circuit and flotation circuit logsheets, flotation feed sizing data, mass balance data and survey assays are presented in Appendix E.



6.4.6 Combined Final Products Mass Balance

Sub-samples were taken from all final products to enable calculation of an overall mass balance. The sub-samples were weighed (wet and dry) to allow calculation of solids in slurry samples, or dry solids contents of wet filter cakes etc. each of the sub-samples was assayed, and the overall final product mass balance is summarised in Table 6-37 , and illustrated in in Figure 6-7:

7. CONCLUSIONS AND RECOMMENDATIONS

Batch flotation tests were conducted on various ore samples, and magnetic product streams to develop a process for reducing sulphur levels to target values. The target total sulphur in magnetite concentrates was <0.5 %, and this level was achieved in 4 of the 6 tests conducted on the DTR/DTW composite sample. None of the flotation tests conducted on the MacDonald and Radford magnetite concentrate samples achieved the target sulphur level, possibly due to oxidation of the pyrrhotite species in these products.

One of the objectives of the pilot plant operations was to assess whether freshly ground and beneficiated ore would alleviate the pyrrhotite oxidation, and produce a magnetite product with a sulphur grade lower than 0.5%. This level was not achieved during the pilot plant operations, however subsequent re-processing of the magnetite concentrate, with excess additions of potassium amyl xanthate and sulphuric acid did produce a low sulphur (0.06%) magnetite concentrate stream.

Due to the complexity of the proposed process flowsheet, continuous operation of the whole process was not able to be conducted. The pilot plant processing was split (decoupled) into 4 separate operations:

- Stage 1A – Comminution of the bulk ore sample to P_{80} of 120 µm, rougher magnetic separation, pyrrhotite flotation on the rougher magnetics, re-grind of the pyrrhotite flotation tailings to P_{80} of 40 µm, cleaner magnetic separation, and pyrrhotite flotation of the cleaner magnetic concentrate.
- Stage 1B – Rougher copper flotation of the Stage 1A rougher non-magnetics, and bulk sulphide flotation on the combined copper rougher tailings and cleaner non-magnetics from Stage 1A.
- Stage 2 – Calcite rougher and cleaner flotation of the Stage 1B sulphide flotation tailings, followed by scheelite rougher and cleaner flotation of the calcite flotation concentrates. The calcite flotation rougher tailings were cyclone de-slimed, and subjected to gravity beneficiation using a combination of spirals and multiple stages of wet tabling to recover a scheelite gravity concentrate.
- Stage 3 – Various product streams from the Stage 2 operations (cyclone overflows, and gravity middlings and tailings) were combined, and re-ground to P_{80} of 45 µm. The re-ground material was subjected to 2 stages of de-sliming, and acidic conditioning with sodium silicofluoride, followed by multiple stages of rougher, scavenger, cleaner and re-cleaner flotation to produce a tin concentrate.

In general terms, the pilot plant operated satisfactorily. Some materials handling issues were experienced on the first day of operation (Stage 1A), mostly associated with settling of milled solids in various slurry transfer lines. A re-configuration of the pumping systems, involving smaller diameter discharge lines, and re-routing of these lines to ensure that vertical transfers overcame materials handling issues.

The other main issues experienced through the piloting operations were related to the small sample mass processed, and the subsequent small mass flow to various stages : scheelite gravity and flotation, and tin flotation. The Client and the Client's Representatives particularly wanted to assess the effects of recirculating various middlings and cleaner tailings streams within the scheelite gravity and flotation operations, and the tin flotation operations. Owing to the low mass of sample reporting to these stages, continuous operations, and closed circuit operations were not possible. An attempt at recirculating wet table middlings was made during the scheelite gravity testwork (Stage 2), however the operations ultimately had to be conducted in batches rather than continuously. Similarly, both the

scheelite and tin flotation cleaning stages were conducted in batches rather than in continuous operation.

The tin flotation did not produce acceptable grades or recovery to the concentrate streams. This is may have been partially caused by changes of pH prior to the flotation arising from de-sliming before and after SSF acidification. Additional water had to be added to the cyclone underflow to achieve the required slurry density, and this addition raised the pH above the batch testwork levels.

If continuous operations of the scheelite and tin circuits need to be conducted, a significantly larger mass of sample must be processed. Approximately 15 tonnes of feed to the magnetic separation stage should generate sufficient non-magnetics to test the scheelite flotation, and tin flotation stages in continuous mode, at a practical feed rate.

Consideration should be also be given to reprocessing the tin flotation scavenger tailings to achieve higher tin recovery, at an acceptable grade.

Comments:-

08:00 Feed on
08:40 - 08:50 Feed off to unblock discharge hose
10:00 Turned Feed off due to inefficient milling. Mill operated to clear out circulating load
11:15 Feed on at reduced rate of 120kg/h
12:25 Feed off to clear blocked hose
13:00 Feed back on
13:15 Feed off. A number of hoses replaced around the circuit.
18.:15 Mill restarted at 100kg/h
18:35 Mill stopped. Blockage of feed pump
18:50 Mill restarted
19:30 Mill stoppped.

Comments:-

23/11/2012 *11:00-12:15 Feed on & off a number off times circulating load in mill too high*

12:30 - Feed back on. Feed rate ~ 40 kg/hr

13:30 - Feed below agitator in feed bulki inconsistent density

15:30 - Feed transferred to 60 L tubs

26/11/2012 *8:30 - Feed to mill feed from 60L agitated tubs*

I/S assumed average of Preflot, Ro & scav tails

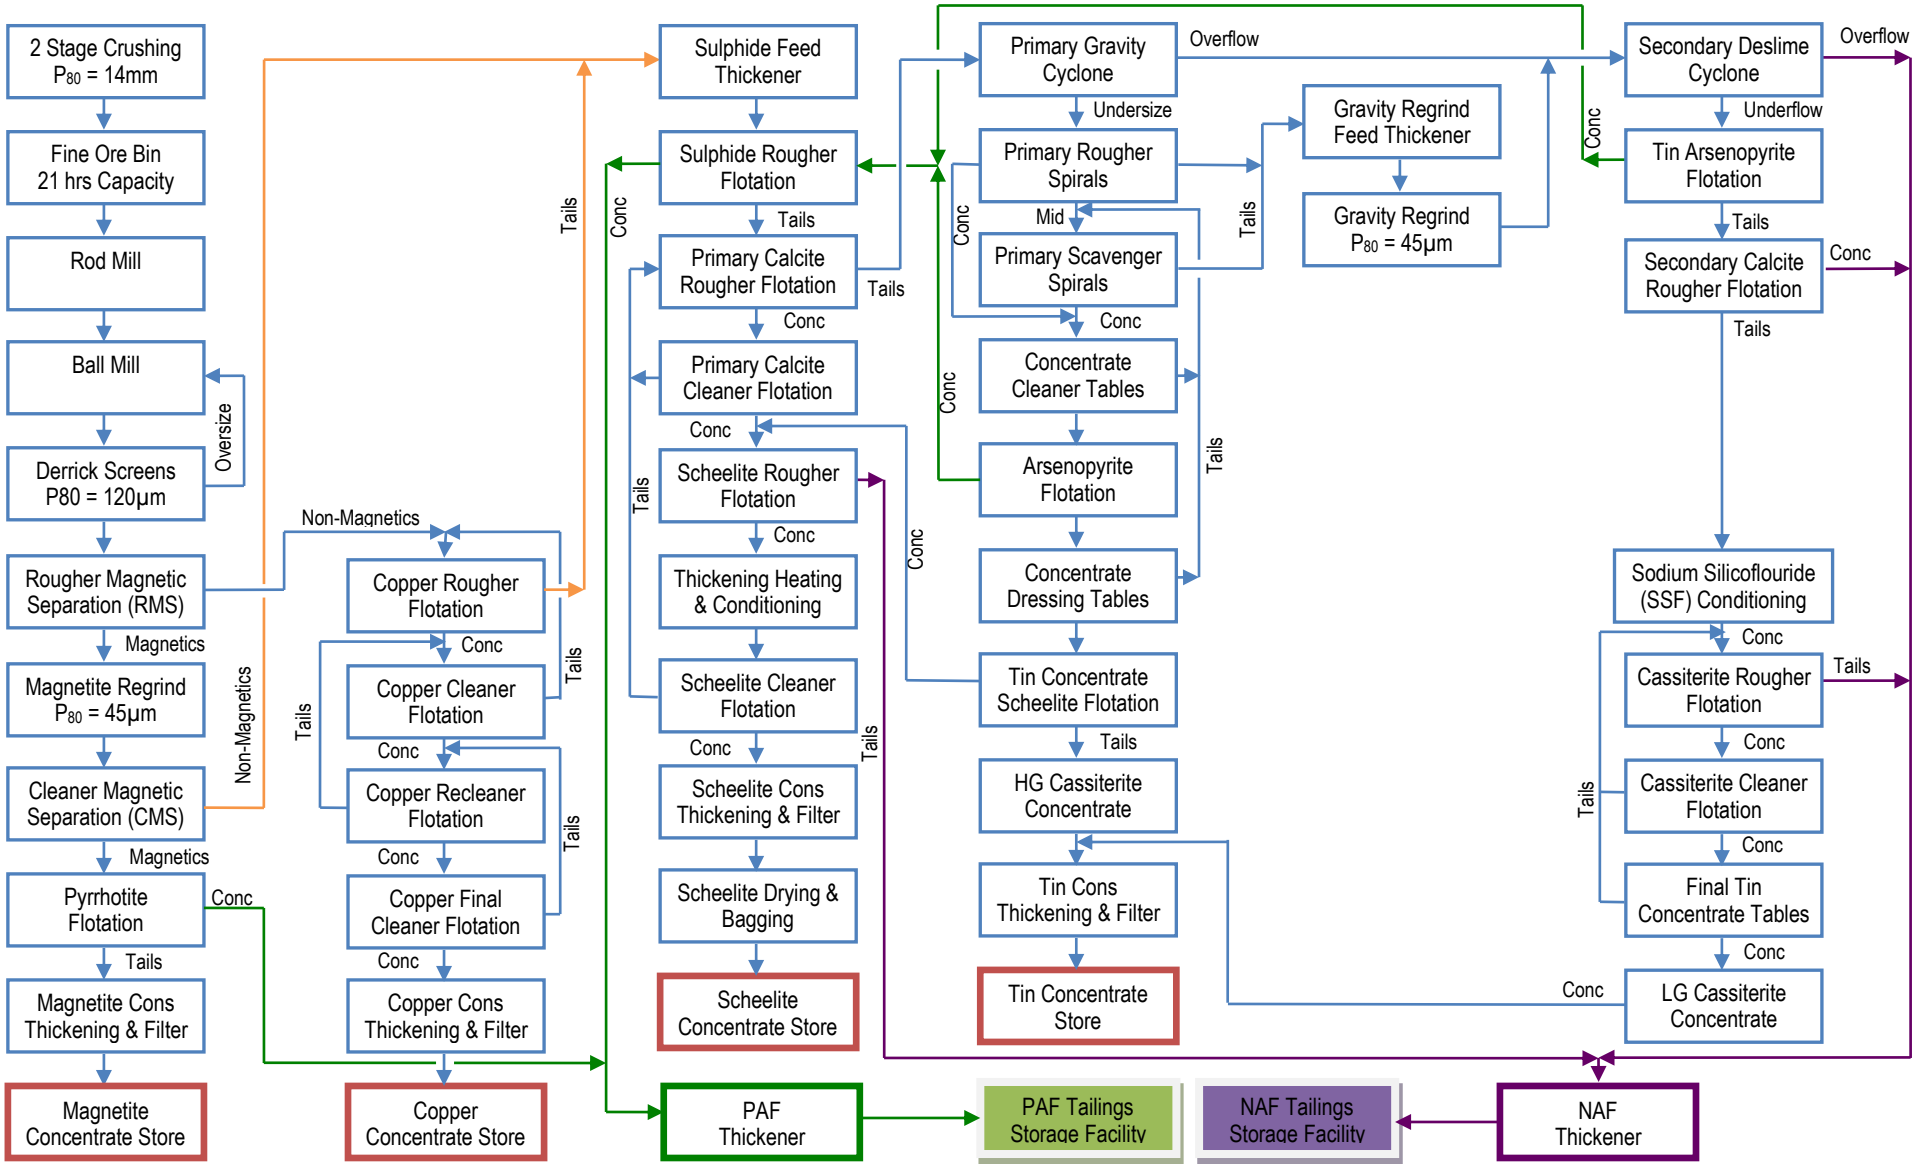
This report has been prepared by SGS Lakefield Oretest Pty Ltd (SGS) at the request of Jason Amaranti of Venture Minerals Limited (Client) under the SGS General Conditions of Service available upon request or at www.sgs.com//terms_and_conditions.htm. Attention is drawn to the limitations of liability, indemnification and jurisdictional issues defined therein..

This Report presents the results of the metallurgical testwork conducted by SGS on the samples (the Samples) provided by the Client.

This Report is provided to the Client on the basis that the Client expressly acknowledges that:

(a) no representations have been made to SGS as to the purpose for which the tests are required to be conducted; and



(b) the Testwork was carried out by SGS on the Samples provided by the Client.

(c) SGS was in not involved in:

- the drilling, collection or transportation of the Samples; and
- the handling of the Samples prior to their delivery to SGS.

By this Report, SGS makes no representation or warranty (express or implied) as to the nature, source, completeness or handling of the Samples and SGS and its directors, employees, agents and consultants denies and disclaims all liability (including for negligence) for any loss, cost, expense or damage arising from the opinions or conclusions contained in this report to the extent that loss, cost, expense or damage arises from the nature, source, completeness or handling of the Samples prior to their delivery to SGS.

SGS expressly denies liability for all damages for loss of opportunity, loss of revenue, loss of actual or anticipated profit or other consequential loss arising either directly or indirectly from reliance by the Client or any other person on the content and conclusions of this report.

Subject: **Super Panning & Magnetic Separation - Report One**

SUMMARY

This is a preliminary or draft note on the performance of the two main ore bodies at Mt. Lindsay that were subjected to magnetic separation at high gauss and super panning. The sample used in these tests was made up by blending equal amounts of sulphide rougher tail (SRT) from No 2 Skarn and Mc Donald's Zone. The sample had been ground to 80% passing 122µm. Results indicate the following on what is termed the Mt. Lindsay Blend.

- This magnetic separation carried out in this test should be considered sighter work and will need to be confirmed by wet high gradient magnetic separation that tat can treat all fractions.
- Up to 90% of the blended SRT is Para magnetic.
- About 20% of the tin occurs as acid soluble tin most of which reports to the Para magnetics.
- Cassiterite recovery on the SRT by conventional gravity separation is predicted to be between 40% and 45% to a high-grade concentrate.
- Scheelite recovery to the non-magnetic was very high at about 90% on the fractions processed.
- Around 90% of the acid soluble tin reports to the strongly Para magnetic fractions.
- If 3,000 gauss is used instead of 8,000 gauss the weight rejection to magnetics is reduced from abound 92% to 72% and tin losses are reduced from about 8% to 4% in the weakly Para magnetic fraction.
- Results indicate that a grind at 80% passing 122µm is about right for maximising cassiterite recovery and confirms that the cassiterite at Mt Lindsay is finer than Renison or Mt. Cleveland.
- The cassiterite observed in the magnetic fractions contained small inclusions, not observed in the cassiterite reporting to the non magnetic and in the one Para magnetic fraction super panned, no scheelite was observed, but the super pan concentrate assayed about 3.8% WO3 suggesting that there might me a very small amount of wolfram present.
- While it was found that scheelite is considerably softer than cassiterite, little sliming into the <8µm fraction was observed and the cassiterite was fond to be highly competent.

Preparation

- About 700grams of both the Main Skarn and No. 2 Skarn SRT's were blended by back riffling five times. Then about 100 grams was riffled out as an assay head sample and about another 100 grams was sized down to <5µm on a size by size basis.

- The remaining 1,030 grams was then screened on a size by size basis down to 38µm and the > 38µm fractions were each subjected to magnetic separation on a dry Rapid cross belt magnet at about 3,000 gauss and then 8,000 gauss. The material was feed slowly to reduce entrainment.

- The Non magnetics were then super panned and super panning was easy as all the gangue minerals were light.

- Time prevented super panning all the magnetic fractions, but the >53µm < 75µm combined magnetics were super panned.

Comments

Overall at this grind size 41 % of the tin and 50% of the tungsten reported to the super pan concentrate. It can also be seen that on the >38µm fractions that 92 % of the SRT is Para magnetic and about 88% f the tungsten and only 58 % of the tin reported to the non magnetics. If these results are expanded to include the < 38µm fractions using the WHGMS, then it is likely that 0ver 90% of the tungsten will report to the non magnetics at a grade of about 4% WO3 when the SRT assays 0.40% WO3. This would mean that the calcite circuit would only be about 14 t.p.h. When treating 156.0t.p.h of ore. Tin recovery to a gravity concentrate would be about 35% to a high-grade gravity concentrate.

	Fraction Feed Assay	52.70	100.00	0.19	0.12	18.1	1.06	100.0	100.0		

Comments

It can be seen that overall tin distribution is only 29% and cassiterite reporting to 37% concentrate, meaning that about 25% of the tin in this fraction occurs as soluble tin. Scheelite recovery concentrate is lower than expected, noting also that most of the soluble tin (≈ 93%) reports to the medium magnetic fraction, estimated at ≈ 3,000gauss, but it is difficult to get a precise reading on the cross belt Rapid. Cassiterite observed under the microscope was light sugary brown, as clean well-formed crystals, no composite were observed. Scheelite glows as off white under the UV light and is shows up as nondescript pale creamy colour under the microscope; Pyrite was prevalent in the concentrate.

Comments

Scheelite recovery has sharply increased in this fraction as has the cassiterite and the vast majority of the soluble tin reports to the Mags I fraction. It is worth observing that the Mags 2 product only contains 7.2% Fe, suggesting that it does not need a lot of iron for a mineral to be Para Magnetic. When observing the concentrate under the microscope the scheelite content more prevalent than the assay suggested, all cassiterite and scheelite grains observed were free.

Comments

When the super pan concentrate was observed under the microscope and UV light, scheelite was more dominant than the assay indicated, all the cassiterite and scheelite grains observed were free. Then Sn & WO3 assays in the Mags 2 fraction are quiet high and most of the tin reporting to this product is cassiterite.

Comments,
The 53µm fraction shows that both scheelite and cassiterite are now liberated and the performance of the Rapid cross belt magnetic separator changes as the Fe content in the Mags 2 fraction increases, as does the soluble ton content. This Mags 2 fraction was super panned and it can be seen that it contained a considerable quantity of “free “ cassiterite. When this cassiterite was observed under the microscope it could be seen that a lot of the cassiterite grains contained black blebs within or on the cassiterite, no scheelite grains observed and is it possible that a small amount of wolfram might be present in the ore? In the Mags 2 super pan concentrate, scheelite recovery increases to 95% overall once the WO_3 in the Mags 2 is added and cassiterie recovery increases to 88.6%.

Comments,
Magnetic separation at this fine size on the dry Rapid cross belt separator is close to the limit of good separation because entrainment becomes a problem and the material starts to stick to the belt, nevertheless results are satisfactory, but in reality losses to the magnetics should be lower than at 53µm.
