SUMMARY

This report summarises the Year 2 activities of EL3/2014. On 8 September 2016, this EL was consolidated into EL 19/2012.

Leached Cap Pty Ltd has undertaken exploration of a 3 km long zone of outcropping silicification close to the Roger River Fault (RRF), primarily located in adjacent EL19/2012. The work to date has been designed to test the concept that the silicification is an intensely leached cap to an epithermal system which may contain gold mineralisation at depth. Low level soil and rock chip anomalies achieved by previous explorers, the presence of warm water springs and mounds along the faulted eastern margin of the Smithton Basin, and similarities between the geology at Roger River and established epithermal gold districts elsewhere, all support this model.

Four lines of Induced Polarisation and Resistivity (IP) were completed in 2014 over the RRF and silicification within contiguous EL19/2012. The IP programme outlined chargeability anomalies to the east of the RRF, and resistivity outlined the RRF as a resistive zone steeply dipping to the east.

The chargeability anomalies showed a possible shallow dip to the east which was the reason for applying for the additional area contained in EL3/2014.

In EL19/2012, hole RRD01 tested one of the chargeability highs and showed it was due to syngenetic pyrite within a sequence of primarily siltstones, shales and sandstones. This pyrite is unrelated to the RRF siliceous zone and therefore is concluded to not be an indicator of mineralization associated with the epithermal system.

RRD01 consequently downgraded the chargeability anomalies and moved the focus for future exploration back to a corridor approximately 1 kilometre wide on either side of the RRF.

During the year, all available aeromagnetic and airborne electromagnetic survey data was re-processed and evaluated. This did not provide any immediate targets for follow-up apart from those already defined by previous mapping.

During the year a small grid-based soil sampling programme at North Whitewater was completed in conjunction with a stream sediment sampling programme.

1. TENEMENT DETAILS

EL 3/2014 is a 10km² licence centred on Duck River, approximately 25 km by road south of Smithton, NW Tasmania (Figure 1). The licence was granted to Leached Cap Pty Ltd (Leached Cap) by Mineral Resources Tasmania (MRT) for a 5 year term commencing on 17th November 2014. The expenditure commitment for the first 2 years was put at \$100,000 by MRT. A Partial Surrender of 5km² was submitted on 16 September from the original 15km².

On 8 September 2016, this EL was consolidated with EL 19/2012.

Land tenure comprises mainly private land which is a mix of beef and dairy cattle farms, and eucalypt plantation owned by Gunns Ltd and remnant native bush. All year round

access to the area is via the bitumen roads Trowutta Road and Roger River Road which run through the centre of the licence for its entire length (Fig. 1).

Figure 1. Location map showing EL3/2014.

2. GEOLOGY

EL 3/2014 covers a northern portion of the Roger River Fault (RRF), a NNE trending major structure transecting Neoproterozoic rocks at the eastern margin of the Smithton Basin/Smithton Synclinorium (Smithton 1:50,000 Geological Atlas Series sheet, Roger and Togari 1:25,000 Digital Geological Atlas Series sheets). The RRF cuts through the eastern limb of a north-plunging synclinorium containing the Neoproterozoic Togari Group. The Togari Group consists of a basal dolomite-chert-lutite sequence (Black River Dolomite), overlain by an interstratified mixed sedimentary and volcanic sequence (Kanannah Subgroup), overlain in turn by the Smithton Dolomite and the Salmon River Siltstone. A distinctive member of the Kunannah Subgroup is a massive basalt unit (Spinks Creek Volcanics).

In the area covered by EL3/2014 and EL19/2012 the precise location of the RRF is commonly masked by surficial sediment cover but it appears to be close to the contact between the Smithton Dolomite to the west and the Kunannah Subgroup to the east. Outcrop of the Smithton Dolomite is restricted to drainage ditches excavated into the flat lying farm land west of the fault and it is reasonable to interpret the fault location as being close to the persistent break in slope at the boundary between the well exposed Kunannah Subgroup on the eastern hill slopes and the largely regolith and soil covered Smithton Dolomite on the flat westerly side of the fault. The current dip direction on the Roger River Fault and the relationship between the fault and discrete zones of silicification are unclear and these are significant issues for the current exploration program, as will be discussed below. Although mapping suggests that the younger Smithton Dolomite appears to be down thrown to the west, implying a normal fault dipping to the west, Everard et al (2007) note that the Black River Dolomite and The Kunannah Subgroup thicken from west to east across the fault zone, suggesting syn-depositional growth faulting and the possibility of an easterly dip, at least during the Proterozoic. By comparison with other major basin bounding faults in western Tasmania it is likely that the Roger River Fault has been through at least two major orogenic deformation events during the Paleozoic and it may have been reactivated again during the regional Cenozoic rifting and volcanism associated with the development of the Bass Basin (Morrison, 2014).

3. EXPLORATION AIMS and PHILOSOPHY

Leached Cap is specifically targeting the zone of silicification which extends for approximately 3 km along the strike of the RRF. Prospectivity for epithermal gold mineralisation at depth beneath the outcropping silica has been established by previous mapping and exploration geochemistry (Turner, 2001, 2003, 2009) and the current exploration program is based on the concept that the outcropping silica represents heavily leached high level capping to an epithermal system analogous to some established gold epithermal provinces elsewhere on Earth (eg. Radtke and Davis, 1990). The presence of geologically juvenile mounds and warm water springs along the eastern margin of the Smithton Basin supports the model.

Davis (2014a) summarises the aims and results for the first two year programme in EL19/2012 which has had a direct bearing on the potential of EL3/2014. The aim of the work was to confirm the relationship between the outcropping silicification and the RRF, to test the current dip direction on the fault and to test for mineralisation at depth. This was to be achieved by a combination of re-interpreting existing magnetics and gravity data, conducting

a new IP survey and the drilling of three targets.

4. SUMMARY OF PREVIOUS EXPLORATION

Previous exploration which has direct relevance to the current programme is restricted to mapping, rock chip and soil geochemistry and on-ground gravity and magnetics, conducted by Greenstone Resources NL and Morrith Holdings Pty Ltd, between 2001 and 2003, on ELs 61/1994, 11/1997, 12/1997, 13/1997, 14/1997 and 17/2001 (Turner, 2002, 2003). some further compilation and interpretation of results from this work was done for Manasia Mining and Metals Ltd on their EL 31/2005 (Turner, 2009).

Mapping demonstrated a series of outcropping bodies of erosion resistant micro crystalline cherty silica with a variety of textures ranging through massive, brecciated, banded, honeycombed and pitted. The outcrop is distributed along a narrow, 3 km long and up to 300 metres wide, zone conformable with the probable sub-crop position of the RRF.

Selective rock chip sampling on outcrop and several east-west lines of soil sampling across the zone detected spotty low level anomalism for; gold (max 15 ppb), arsenic (max 1273 ppm), antimony (max 30 ppm), copper (max 886 ppm), zinc (max 510 ppm) and lead (max 302 ppm). One rock chip sample from outcrop in an abandoned road aggregate quarry at Roger River (approximate location 336550E, 5457600N MGA) included visible barite and assayed almost 6% barium and 1.5 ppm mercury (Turner, 2003).

No follow up field work was conducted on this target prior to the current programme commenced by Leached Cap.

5. GEOCHEMISTRY

As foreshadowed in Davis 2014b, in April 2016 Consultant geologist Ken Morrison supervised a stream sediment sampling programme and a 50x50m and 50m x 100m C-horizon soil sampling programme at the North Whitewater prospect and within the Duck River and Roger River ELs.

Figure 2 shows a plot of the C-horizon sampling results which are listed in the Appendices I and II and the results of each shown on Figure 2.

The following descriptions were provided by Ken Morrison:

Methods

1) Soils

80 C-horizon soil samples were taken on a gridded pattern centred on a base line tracking the projected position of the target linear structure (Figure 2). Land use on the area covered is a mix of eucalypt plantation and beef cattle pasture, with minor belts of native vegetation (Figure 2). Substantial weed infestation, especially by blackberry, exists through the plantation and the remnant adjacent native forest. Both the forestry company (FGI-Australia Pty Ltd) and the freehold farmers were helpful and cooperative regarding access and no vegetation cutting was required to access the sample sites.

Basal soils including bed rock chips were encountered at depths ranging from 10cm to 2.2m, with the deeper samples drilled by hand auger and the shallower sites sampled by trenching tool. Achieving genuine C-horizon intersections with abundant rock chip regolith was uncertain on two or three of the deep soil profile sites in the paddock west of Trowutta Road, at the southwest end of the grid (Figure 2). Bedrock lithology also exerts control over rock chip hardness, with soils on silicified carbonate and chert weathering much less than the softer basaltic siltstones and polymict lutites of the Keppel Creek Formation. Details of each sample are tabulated in Appendix II.

Samples of approximately 2 kg average weight were bagged and submitted to the Burnie ALS depot for drying, pulping and assaying for gold by 50g fire assay/AAS (0.2ppb detection limit) and arsenic by ICP-AES (2ppm detection limit).

2) *Stream Sediments*

14 sites on creeks and small rivers spread over a northeast-southwest distance of 7 km were sampled (Figure 3), with the aim being to test for discrimination between regional background and an anomalous zone, especially for ultra-fine gold. Sites which qualified for sampling showed evidence of transported sediment and had some running water, although in the smaller creeks with minimal water flow and a high mud content, sumps were dug into the creek bed to enable sampling and sieving of a reasonably uniform sample type.

Sampling method involved wet sieving bed load sediment through a 2mm sieve on top of a pan, until 2 litres of -2mm product was recovered. Free water was drained off and the bagged samples were submitted to the Burnie ALS depot for drying and mechanically dry sieving to produce a -80 mesh fraction. Details of each sample are tabulated in Appendix I.

The -80# fraction was pulped and assayed for gold by 50g fire assay/AAS (0.2ppb detection limit) and arsenic by ICP-AES (2ppm detection limit), ie the same program as applied to the soils.

The residual +80# -2mm fraction was retrieved from the lab and panned down to a concentrate estimated to be approximately 50g (ie equivalent to a single fire assay charge) and then re-submitted to ALS for gold and arsenic assaying as per the -80# fraction.

Figure 2. Map showing the C-horizon soil sample locations and stream sediment locations with number and the Au and As assays.

6. EXPENDITURE

Expenditure for the year to 8 September has been primarily on the geochemistry programme.

Category	Cost \$
Geology	13,495
Admin & other costs	811
Total	14,306

7. ENVIRONMENTAL ISSUES

Field work involving non-invasive soil, stream sediment and rock chip sampling were conducted in these areas and there have been no environmental issues.

8. PLANNED PROGRAMME

In the new consolidated tenement, EL19/2012, preliminary results of compilation of historical and new data indicate that the recent C-horizon soil sampling results indicate that several As anomalies are not closed off and that anomalous gold results at up to 6x background, and historical results in the northeast of the tenement will likely require further investigation.
