1. SUMMARY

Exploration licence 16/77 was granted on the 23rd December, 1977 for a period of six months. During the initial six month licence period the area was geologically mapped.

Mapping has indicated a 300 metre thick section of the Upper Triassic Age, Upper Parmeener Super Group coal measure sequence in the Royal George/St.Pauls River Valley. Economically developed coal seams appear to be restricted to the upper 150-200 metre thick section of the coal measures. Four areas within the St.Pauls River Valley appear to hold some potential for coal. Exploratory drilling is required in each of these four areas to determine the presence of economically developed coal seams.

Calculated coal reserves are 790 000 tonnes insitu for a restricted area east/northeast of the old Merrywood Mine. Insufficient information and geological uncertainty precludes the calculation of reserves in other portions of the E.L., even in the inferred category.

The coal is of a low rank bituminous type with an Australian Classification Number of 501(5). Generally, the coal has a dull vitreous lustre and a low reactives content (vitrinite + exinite) of less than 20% by volume. The coal is unsuitable for coke making or as a coking coal blend fraction because of its poor coking properties and low reactives content. Ash content of washed coal is usually 18-22%, which restricts possible usage to steam raising or use in cement manufacture.

2. INTRODUCTION

The exploration programme within the initial six month licence period involved literature research, reconnaissance and detailed mapping in order to outline potential areas of interest for exploratory drilling. Mapping was essentially concentrated on the delineation of the Triassic Age Upper Parmeener Super Group coal measure sequence. A number of coal seams occur within these measures, one of which is currently mined northeast of the exploration licence (E.L.) at the Duncan Coal Mine at Fingal and one was previously worked within the E.L. at the Merrywood Mine.

The Lower Parmeener Super Group, Mathinna Beds, granite and dolerite were also mapped.

The topographic base for the geological map was prepared from the 1:100 000 St. Pauls and Break O Day topographic sheets. Field mapping was on a combination of 1:40 000 aerial photographs and 1:30 000 topographic base plans.

Previous workers on the coal measures within the E.L. were :-

Blake, P. (Snow Hill Quadrangle)
Hills, C.L. et al (1922)
Hughes, T.D. (1960)
Threader, V.M. (1968)
Western Mining Corporation (1977)

The Tasmanian Department of Mines have also drilled four diamond drillholes within the E.L. as part of their regional coal drilling programme. These holes are DDH18 (Merrywood), DDH22 (Lochaber), DDH28 (Base of Vertical 'Acre') and DDH29 (Top of Vertical 'Acre').

3. LICENCE DETAILS

On the 20th October, 1977 an area of 545 km^2 was pegged for consideration by the Director of Mines as an Exploration Licence (E.L.). Subsequently E.L. 16/77 was granted on the 23rd December, 1977 for a period of six months up to the 23rd June, 1978. The area granted was 545 km^2 less the Departmental Reserve Areas Numbers 167 and 196 in the northern portion of the E.L.

On the 7th April, 1978 the Mines Department advised that the Reserve Areas 167 and 196 would be revoked for a period of 48 hours from noon on Wednesday 26th April, 1978. Consequently, an area of 220 km^2 conforming to the portions of the reserve areas lying within the E.L. was pegged at 12.30 p.m. on the 26th April, 1978 for addition to E.L. 16/77.

On the 19th June, 1978 application was made to the Mines Department for a six month extension of the E.L.

4. CLIMATE

The climate is of a cold temperate type, with rainfall increasing from west to east. Rainfall ranges from 500 mm in the west up to 875 mm in the east of the E.L. In the higher plateau areas rainfall is generally in excess of these figures.

5. ACCESS

The licence area is located approximately 80 km southeast of Launceston. Road distances to Hobart and Launceston are 185 km and 98 km respectively from Royal George, via the Royal George-Avoca road, South Esk Highway and Midlands Highway.

The St. Marys-Conara Junction branch railway line passes through the northwestern portion of the E.L. Conara Junction lies on the main Hobart-Launceston railway. The closest accessible rail facilities to the Royal George area are located at Avoca, which lies 84 km from Launceston and 185 km from Hobart by rail.

Access within the licence area is via the Avoca-Royal George-Old Coach Road in the south and the South Esk Highway in the north. Other access is via the Merrywood-Mt. Foster Road and the Tasmanian Pulp and Forest Holdings (TPFH) MS and MG roads. Numerous other logging side tracks branch off the Mt. Foster and TPFH roads.

During periods of heavy rain flooding in the St. Pauls and Swan Rivers prevents access to Royal George. River crossings along the Avoca-Royal George Road, Old Coach Road (Waters Meeting), Merrywood Road and MS Road (Rajah crossing) are subject to flooding and were impassable three times during the initial 6 months licence period.

6. TOPOGRAPHY

The topographical units with the E.L. are from north to south, the South Esk River Valley, the Mt. Foster-Fingal Plateau, the St. Pauls River Valley and the Snow Hill/Lewis Hill/Reynolds Hill Plateau. The Swan River Valley lies in the southeast corner of the E.L. The three river systems have dissected the plateau areas.

Elevation within the E.L. ranges from 220 metres on the valley floors to in excess of 1000 metres on Mount Foster.

The South Esk and St. Pauls River Valleys have been cleared and are used for grazing and some cultivation. Tasmanian Pulp and Forest Holdings (TPFH) is currently cutting timber for woodchip on the plateaus within the E.L.

7. GEOLOGY

7.1 Regional

Exploration Licence 16/77 is located on the northeastern margin of the Permo-Triassic Tasmania Basin. Hale (1962) recognized Jurassic plant zones in specimens from Mt. Nicholas, indicating that sedimentation extended into the Jurassic within some parts of the basin.

The basin basement consists of the Lower Palaeozoic Mathinna Beds and the Devonian Age Ben Lomond Granite.

A generalised stratigraphic column for the area is as follows :-

Alluvium and Dolerite Scree		Quaternary
Basalt		Tertiary
Dolerite		Jurassic
Parmeener Super Group	Upper Parmeener Super Group (Disconformity)	Triassic
	Lower Parmeener Super Group (Unconformity)	Permian
Ben Lomond Granite		Devonian
Mathinna Beds		Lower Devonian - Early Ordovician

~48009A

The Parmeener Super-Group was set up to divorce the "Permian" and "Triassic" myths. The Permo-Triassic time boundary goes through the upper Parmeener somewhere towards the base. This time boundary is NOT DISCERNIBLE in the field.

We have two lithologic stratigraphic units — upper & lower Parmeener but these are not chronostratigraphic units

7.2 Mathinna Beds

The Mathinna Beds are Lower Palaeozoic Age (Cambrian or Early Ordovician-Lower Devonian) slates and phyllites overlain by a sequence of interbedded lithic sandstone and mudstone. The beds have been folded on a NW-SE axis, and are well exposed along the south Esk Highway in the N.W. corner of the E.L. between Tullochgorum Estate and Fingal. Other exposure of the beds within the E.L. is restricted to a small area of outcrop west of Royal George.

7.3 Parmeener Super Group

The Parmeener Super Group is divided into lower and upper sections of Permian and Triassic age respectively. The two sections are disconformable. The super group contains three coal measure sequences, two occurring in the Permian section and the third within the Triassic. Within the E.L., coal seams of economic potential are restricted to the Triassic Age coal measure sequence.

NOT SO.

7.3.1 Lower Parmeener Super Group

The Lower Parmeener Super Group unconformably overlies the Mathinna Beds. The contact is well exposed in Tullochgorum Creek and Iron Pot Gully in the N.W. of the E.L.. In the south, the contact is exposed in old tin workings west of Royal George at M.R. 697 678 (St. Paul's 1:100 000 sheet). The total Permian section within the E.L. is in the order of 100-150m thick. No complete exposed section is present within the licence.

The Permian Age Lower Parmeener Super Group within the Fingal-Royal George area is divided into basal conglomerate, Mersey Coal Measures, Cascades Group and Ferntree Group in ascending stratigraphic order. The Cygnet Coal Measures which lie at the top of the Permian sequence do not occur within the E.L..

The section commences with a basal conglomerate that varies in type and thickness throughout the area. The conglomerate appears to have been derived from the Mathinna Beds in the northeast of the E.L. and from both granite and the Mathinna Beds near Royal George. Thickness is variable, ranging from 1-15 metres.

The basal conglomerate is overlain in some parts of the area by a thin section of the Lower Permian Age Mersey Coal Measures which appear to have been deposited in small localised depressions. The measures were originally thought to be equivalent to the Artinskian Greta Coal Measures in N.S.W. However, they are now thought to be of Late Sakmarian-Early Artinskian age and thus pre-date the Greta Coal Measures. Thickness of the measures was difficult to determine from surface outcrop, but appears to range from 0-15 metres. The sediments consist of fine-medium grained quartz lithic sandstone, grey mudstone, carbonaceous mudstone and very minor shaley coal. The coal found in outcrop was only 0.10 metre thick. The measures have no economic potential within the E.L. They outcrop north of the licence near Fingal and then thin to the southwest, disappearing in the vicinity of Iron Pot Gully.

The overlying marine Cascades Group comprises a sequence of mudstone and siltstone overlain by limestone. The lower mudstone/siltstone unit is up to 40 metres thick and is often fossiliferous. The limestone is usually highly fossiliferous and ranges in thickness from 10-50 metres. The group outcrops in the St. Paul's River Valley near Royal George and in the northwest of the licence.

The Ferntree Group appears to conformably overlie the Cascades Group, although no contact was found outcropping within the licence. The Ferntree Group comprises the Risdon Sandstone in the lower section and a dark grey silty mudstone-siltstone with occasional quartz grains and pebbles in the upper section. The Risdon Sandstone was not recognized in outcrop. The upper mudstone-siltstone unit ranges in thickness from 25-50 metres. No marine or plant fossils were found within this group.

7.3.2 Upper Parmeener Super Group

Various sub-divisions of the Triassic sequence have been proposed but are now considered obsolete. Thus, the Triassic is now referred to as the Upper Parmeener Super Group with no further sub-division.

No drillholes within the exploration licence have intersected the complete Triassic coal measure sequence. However, Mines Department drilling to the northeast of the E.L. intersected an apparently complete section in the order of 320 metres thick. The section is in the order of 350 metres thick near the eastern margin of the E.L., in the vicinity of Coal Rivulet - Meadstone Saddle. South of Royal George, the section has thinned to approximately 300 metres and appears to continue thinning to the west. The westerly thinning of the coal measures appears to be a result of non-deposition (offlap) in the upper portion of the section, as evidenced by the presence of a cobble conglomerate 10-30 metres below the top of the measures east of Meadstone Saddle and its absence to the west. The conglomerate is a useful marker unit in the eastern portion of the E.L., and further to the east in the I.M.I./Shell E.L. Thickness of the measures intersected in Department of Mines drillholes DDH18 and DDH29 on the Mt. Foster - Fingal Plateau was 47m and 79m respectively. In these two holes, only the lower section of the coal measures is present because of the intrusion of dolerite sills.

Outcrop of the coal measures in the valley floors and upper valley slopes is generally poor, due to alluvium and

dolerite scree. However, good exposures of the coal measures and coal seams commonly occur within the various creek beds.

The Triassic coal measure sequence consists of quartz sandstone with interbedded mudstone, siltstone and rare coal in the lower section and lithic sandstone with interbedded mudstone, siltstone, carbonaceous mudstone and coal in the upper section. Coal seams are further discussed in Section 8 of this report.

The lithic sandstone in the upper section of the measures has been previously referred to as a feldspathic sandstone by Nye (1921), Hills (1922), Hills and Carey (1949), Banks (1958), Jennings (1955) and Threader (1968). Surface mapping and the four Mines Department drillholes within the area indicate that the thickest coal seams occur within the upper 200 metres of the coal measures, and that the lower 100 metre thick quartz sandstone section is usually barren of coal.

The quartz sandstone and interbeds in the lower section of the coal measures appear to thin to the east. South of Royal George the quartz sandstone appears to be up to 100m thick, whereas to the east at Red Rock it appears to be only in the order of 60-80m thick. In some parts of the area a thin pebble conglomerate/granular conglomerate occurs at the base of the Triassic. The Permian/Triassic contact (?) was observed in outcrop at only one locality within the licence in Rockhouse Creek at MR 774694 (1:100 000 St. Paul's sheet). At this locality a basal conglomerate approximately 1.0m thick disconformably overlies a dark grey silty mudstone (Upper Permian Age Ferntree Group?). The conglomerate consists of pebbles of quartz, quartzite, volcanic, mudstone and mudstone lenses in a sandy kaolinitic matrix.

7.4 Cainozoic

7.4.1 Tertiary

Tertiary sediments and basalts occur to the west of the licence in the St. Paul's and South Esk Valleys near Avoca as valley infillings. No Tertiary age sediments or basalt have been identified within the licence area.

7.4.2 Quaternary

Quaternary sediments are common within the licence and comprise alluvium on the St. Paul's and South Esk River Valley floors and dolerite scree on the valley slopes and plateaus.

The alluvium consists of silt and sand on the valley floors and swampy loam in the marshes on the plateaus. In the broader sections of the St. Paul's and South Esk River Valleys the alluvium is believed to be up to 85 m thick.

A borehole drilled in the bed of the South Esk River at Tullochgorum terminated in alluvium at a depth of 82.2 m (Krause 1890).

Dolerite scree is common along the edges of the tiers and valley slopes. The scree ranges in size from particles up to blocks in excess of 10 m in diameter. On the northern slopes of Mt. Foster some of the dolerite blocks are in the order of 10-15 m. The abundance of dolerite scree on the slopes and in creek beds masks the dolerite/sedimentary contacts and complicates mapping and location of coal seams. In some creek beds exposed weathered dolerite scree is similar in appearance to weathered lithic sandstone. Thickness of the dolerite scree appears to vary from a thin veneer up to an estimated thickness of 100 m on the northern slopes of Mount Foster.

7.5 Igneous Rocks

7.5.1 Devonian Granite

The Upper Devonian age Ben Lomond granite intrudes the Mathinna Beds in the vicinity of Royal George. The granite occurs in outcrop as low rounded hills and appears to have had some residual relief when the Permian age Lower Parmeener Super Group was being deposited.

Tin mineralisation was associated with the intrusion of the granite and a number of tin mines have operated near Royal George.

7.5.2 Jurassic Dolerite

The dolerite is of Upper Jurassic Age and intrudes the Parmeener Super Group as a complex of sills, transgressive sheets and dykes. Within the E.L. the dolerite usually intrudes the Upper Parmeener Super Group. North of Fingal the dolerite has been reported by Threader (1968) to intrude the Lower Palaeozoic Mathinna Beds. Dolerite outcrops over approximately 60% of licence area as plateau areas, due to its widespread intrusion and general resistance to weathering and erosion.

The dolerite sills range in thickness from 2 m in Hockeys Creek up to 371.50 intersected in Department of Mines drillhole DDH18 (north of Merrywood at MR792 765 St. Paul's 1:100 000 sheet). The sills generally appear to have a thickness in excess of 200 m, especially the main 'upper sill' which forms the Mt. Foster-Fingal plateau. This 'upper sill' which has been exposed by erosion and

caps the plateau appears to be a number of abutting sills formed from separate feeders. Some parts of the Mt. Foster-Fingal plateau dolerite appear to be transgressive sheets or dykes, such as the dyke(?) southeast of Fingal,and the transgressive sheets (?) at Pratts Hill, Dickies Ridges-Meadstone Saddle and Cut Off Hill-Mt. Misery. Other transgressive sheets(?) occur at Leipzig Bluff-Mt. Henry and south of Snow Hill homestead.

The intrusion of the dolerite at levels lower than the upper main coal bearing section of the Triassic Coal Measure sequence appears to have considerably reduced the economic coal potential over large portions of the E.L. Intrusion in the lower levels of the measures has resulted in the upper coal bearing portion being up-rafted and subsequently removed by erosion. In the north and northwest the dolerite appears to have been intruded at or near the base of the Upper Parmeener Super Group. This could not be directly confirmed by mapping in the northwest corner of the E.L. along the northern slopes of Mt. Foster because the lower dolerite contact was masked by dolerite scree. However, in Mines Department DDH18 and DDH29 on top of the Mt. Foster-Fingal Plateau, the thin lower barren coal measure section intersected, indicates intrusion near the base of the measures.

In the St. Paul's River Valley near Royal George, the dolerite has been intruded near the top of the coal measures and has an elevation of 600-700 m above sea level.

Contacts between dolerite and sedimentary rocks were observed at only two localities within the licence. These contacts were in Hockeys Creek at MR 775 743 St. Paul's 1:100 000 sheet and in Lucks Creek at MR 854 782 Break O'Day 1:100 000 sheet.

In Lucks Creek the contact occurred at an elevation of approximately 520 m. The contact consists of fine grained (chilled) dolerite with numerous vertical cooling joints (0.01-0.03 m spacing) conformable with a light grey baked claystone (or mudstone) 0.32 m thick which is underlain by a fawn coloured friable siltstone. The baked claystone is hard and brittle with conchoidal fractures and contains remnant carbonaceous plant fragments. The baked claystone is similar in appearance to a porcellanite. The dolerite at this locality forms part of the Mt. Foster-Fingal Plateau sill. The absence of coal seams exposed in the Lucks Creek outcrop section suggests that the dolerite sill intrudes toward the base of the upper lithic sandstone section of the coal measures.

In Hockeys Creek, a thin sill 2.0 m thick intrudes the middle section of the coal measures.

7.6 Structure

The Permo-Triassic sedimentary sequence within the E.L. lies on the northern margin of the Tasman Basin.

The basement consists of the Lower Palaeozoic Age Mathinna Beds which have been intruded by Upper Devonian Age Ben Lomond Granite. The basement surface is reported by Threader (1968) to be planar, with a 1^{o} or less southerly dip where the Mathinna Beds are exposed north of Fingal. In the northwestern corner of the E.L. the basement surface also generally appears to be planar with a dip of approximately 1^{o} to the southeast. In the vicinity of Royal George where the exposed basement is granite, the surface appears to have been irregular and had some residual relief during deposition of the Lower Parmeener Super Group. Estimated height of the granite 'hills' appears to have been in the order of 50-80 metres during deposition of the Lower Parmeener Super Group. However, some of this apparent relief could be due in part to Jurassic or Tertiary faulting.

The Permian sequence within the area appears to have a regional dip of $3-4^{o}$ to the southeast. The disconformably overlying Triassic sequence has a slightly steeper dip of $3-5^{o}$ to the southeast. Although the regional dip is $3-5^{o}$ to the southeast it is often variable and dip reversals occur, suggesting that the beds are possibly warped or undulating. This apparent warping or undulation of the beds possibly results from the intrusion of the dolerite. Steeper dips are common throughout the area, especially near Merrywood, Leipzig Bluff and Tullochgorum Creek.

DIPS - MERRYWOOD OPEN CUT.

GEOLOGIST: D. D. WATERS.	SCALE: 1:10,000
DRAWN: M. P. DONOVAN.	REPORT No: 985
DATE: 12-9-78.	

Dips of 10-15° are common along the edge of the tier west of Merrywood and in parts of the Old Merrywood open cut and underground workings.

Within the open cut dips are variable, ranging from 2-30° (see Figure 1). The dip of 30° to the southwest in the northwest corner of the open cut appears to be a result of hill creep or slumping, rather than folding or faulting.

Near Leipzig Bluff, at MR 812 678 St. Paul's 1:100 000 sheet, dips of 68° to the east occur adjacent to the dolerite. The steep dips appear to be related to the intrusion of the dolerite. Similarly in Tullochgorum Creek, at MR 778828 St. Paul's 1:100 000 sheet, southerly dips of 85° occur near the dolerite contact.

No folding was observed in the Permo-Triassic sequence within the E.L., apart from minor warping of the beds possibly due to the intrusion of the dolerite.

Both minor and major faulting occurs within the area, though the full extent of faulting is masked by the extensive Jurassic Age dolerite sills and Quaternary dolerite scree. Faulting within the E.L. appears to have been associated with the intrusion of the Jurassic dolerite and Early Tertiary block movements. The E.L. is located midway between the Castle Carey Fault in the west and the Cornwall Fault in the east.Figure 2 shows the Tertiary Fault Systems on the northeastern margin of the Tasman Basin, modified after Threader (1968).

GEOLOGIST: D. D. W.	SCALE:
DRAWN: M. P. D.	REPORT No: 985
DATE: JULY, 1978	

The main fault within the area is a northeast-southwest trending fault extending from Meadstone Saddle, through Red Rock and south of Royal George. The northwestern block is upthrown with respect to the southeastern block. The continuation of the northeast-southeast fault south of Fingal into the Mt. Foster Plateau by Threader (1968), does not appear necessary. The southern extension of the fault appears to be based on a series of cross sections by Threader (1968) assuming constant regional dip and presence of the Triassic coal measures on the northern slopes of Mt. Foster. Surface mapping has indicated variations in the regional dip and possible absence of the coal measures on the northern slopes of Mt. Foster.

Other smaller faults appear to be present within the area. Trend lines as interpreted from air photos of the area are shown on Plate 2. A number of these appear to be related to possible faults.

8. COAL SEAMS

8.1 General

Coal seams of economic potential within the E.L. are restricted to the Triassic Age Upper Parmeener Super Group coal measure sequence.

Coal has been previously worked within the E.L. at a small open cut and underground mine located at Merrywood. Total production was 423 475 tonnes up to closure of the mine in 1961.

Small amounts of coal were also mined in a prospect tunnel and adit located at Lewis Hill and south of Royal George respectively, prior to 1920. The prospect tunnel on Lewis Hill is located in Rockhouse Creek at MR 772 662 (St. Paul's 1:100 000 sheet) and was reported to have opened a seam 1.83 m (6') thick (Hills, 1922, page 215). The adit south of Royal George is located in Stable Creek at MR 735 638 (St. Paul's 1:100 000 sheet) where it is reported a 1.83 m (6') thick seam was exposed (Hills, 1922, Page 216).

Surface mapping, Mines Department drillholes and old tunnels and mine workings within the licence indicate that the thicker potentially economic coal seams occur within the lithic sandstone section in the upper 200 metres or less of the coal measures. Hills (1922) identified eight coal seams named the Alpha, Beta, Gamma, Delta, Eta, Theta, Iota and Kappa Seams in descending order within the 'feldspathic' sandstone (lithic sandstone). Hills correlated the seam worked at Merrywood as the Beta and indicated that the same seam was also exposed in the prospect tunnel at Lewis Hill and adit south of Royal George.

This correlation appears to have been on the basis of thickness, as Hills (1922) could not locate either the prospect tunnel or adit during field mapping.

The seam nomenclature of Hills (1922) is not in current use because of the difficulty in correlating the coal seams over short distances within the Fingal-Cornwall-Merrywood area. Seams are therefore given local names. The seams also appear to be lenticular, and have possibly formed within a number of sub-basins.

8.2 Coal Outcrops

Coal outcrops found during surface mapping were confined to the Royal George/St. Paul's River Valley portion of the licence. Thickness of the seams outcropping ranges from 0.06 metres up to 3.38 metres at Merrywood open cut.

The coal outcrops in the various creek beds are listed below :-

Merrywood Creek	-	1.52 m section of Merrywood Seam at MR 797749(A)
Cut Off Hill Creek	-	0.10 m at MR 890 776(B)
	-	0.42 m at MR 888 784(B)
Coal Rivulet	-	2.87 m at MR 907 766(B)
	-	0.65 m at MR 912 766(B) (Note: The Coal Rivulet outcrops are outside E.L. 16/77)
Barn Hill Creek	-	0.30-0.45 m Coal/shale at MR 878 737(B)
	-	0.20 m at MR 878 735(B)
	-	0.45 m Carb.mudstone at MR 878 733(B)
	-	0.45 m at MR 877 732(B)
	-	0.15 m at MR 876 731(B)
Woodheads Creek	-	0.60 m at MR 706 866(B)
	-	0.52 m at MR 708 865(B)
Leipzig Bluff Creek	-	0.17 m Coal/Carb. mudstone at MR 812 677(A)
Lewis Hill Creek	-	0.47 m at MR 787 668(A)
Rockhouse Creek	-	0.88 m at MR 776 666(A)
	-	0.13 m at MR 773 665(A)
	-	0.15 m at MR 773 665(A)
	-	1.83 m (Prospect Tunnel) at MR 772 662(A)
Stable Creek	-	0.57 m at MR 740 651(A)
	-	0.49 m at MR 735 638(A)
	-	0.20 m at MR 727 633(A)

Note: (A) designates the St. Paul's 1:100 000 topographic sheet.

(B) designates the Break O'Day 1:100 000 topographic sheet.

A log and description of each of the coal outcrops given above appears in Appendix I. Apart from the Merrywood Seam outcropping in Merrywood Creek and the 2.87 m thick seam in Coal Rivulet (located outside eastern boundary of E.L.) the outcrops were less than 1.00 metre thick.

In addition to the above coal outcrops, dull and dull banded coal fragments were also found in Brookstead and Hockeys Creeks west of the Merrywood Mine.

8.3 Drillhole Intersections

Of the four Mines Department Drillholes located in the E.L. coal was intersected in only DDH22 'Lochaber' at MR 863 734 'Break O'Day' 1:100 000 sheet and DDH28 at MR 822 868 St. Paul's 1:100 000 sheet. Graphic and written logs for holes D.M. DDH18, DDH22 and DDH28 are given in Appendices II and III respectively.

Coal intersections in holes DDH22 and DDH28 are given below:

	Roof Depth (m)	Floor Depth (m)	Thick. (m)	Recovery (m)
DDH22	79.28	79.83	0.55	0.46
	155.19	156.81	1.62	1.49
	169.90	170.48	0.58	0.56
	182.44	182.77	0.33	0.32
	188.59	189.32	0.73	0.68
	199.30	200.15	0.85	0.85
DDH28	213.26	43.66	0.40	0.39
	63.21	63.71	0.50	0.50

The thickest seam intersected was in hole DDH22 at a depth of 155.19 - 156.81 metres. Recovery for this 1.62 m thick section was only 1.49 m.

8.4 Merrywood Coal Seam

This seam has been mined by both open cut and underground mining operations at the Merrywood Mine. The seam has a maximum recorded thickness of 3.38 m, but has an effective working section of less than 2.74 m. The upper 0.64 metres of the seam consists of interbedded coal, carbonaceous mudstone, claystone and grey mudstone. The seam has a thick grey mudstone roof and floor. A section of the seam is given in Appendix I.

Mining conditions in the underground mine were difficult because of the incompetent mudstone roof and steep grades in the northern extremities of the workings. Underground mining was of a bord and pillar type, though no pillars were mined because of the poor roof conditions.

Extension of the seam under the dolerite to the north and east of the old workings appears doubtful on present information.

8.5 Lewis Hill Prospect Tunnel

This tunnel is located in the northwestern bank of Rockhouse Creek at MR 772 662 St. Paul's 1:100 000 sheet. The tunnel was mined in the 1910-1920 period by Crisp, a relative of the present owner of Lewis Hill Homestead. The roof of the seam is only slightly above creek level, and as a result the tunnel has been infilled by

creek wash. The seam was reported to be 1.83 m thick (6') and has a medium grained lithic sandstone roof in excess of 4.0 m thick. The coal and sandstone roof appear to be separated by 0.15 m of carbonaceous mudstone. Hills (1922) correlated the Lewis Hill prospect tunnel with the seam at the Merrywood Mine on the basis of thickness. However, on the basis of a thick grey mudstone roof at Merrywood and a thick sandstone roof at Lewis Hill, the correlation appears doubtful.

8.6 Stable Creek Adit - South of Royal George

This old adit is located in Stable Creek at MR 735 638 (St. Paul's 1:100 000 sheet). The seam was reported to be 1.83 m thick (6') by Hills (1922). The thickness could not be confirmed because the adit has collapsed. A seam outcropping in the creek bed at approximately the same level as the adit had a thickness of 0.49 metre, with a laminite of sandstone/mudstone for the roof and floor.

9. COAL QUALITY

The Triassic Age coal in the E.L. is low rank high volatile bituminous. Classification of the coal according to various authorities is as follows :-

Australian	International	NCB	ASTM No.	ASTM Descr.	Seyler's Descr.
501(5)	401	901	II3	High Vol A. Bitum	Sub hydrous

The coal is relatively hard and has a dull vitreous lustre and sub-conchoidal fracture. The seams outcropping in the creek beds within the area consist mainly of dull coal. For example, in the seam exposed in the open cut at Merrywood, the breakdown of the coal on a brightness basis is as follows :-

Dull coal	62%
Dull banded (minor bright)	36%
Bright coal	2%

The bright coal usually occurs in bands less than 0.05 m thick. The bright bands usually have well developed cleat and abundant talc coatings. In the dull banded coal the minor bright coal component occurs as thin laminations and lenticular bands.

The coal typically has a low reactives to inerts ratio, resulting from extremely low vitrinite and exinite contents. The reactives (vitrinite + exinite) generally total less than 20% by volume, similar to that of the Upper Triassic Age Callide Coal in Queensland. The low reactives content and poor caking indices deem the coal unsuitable for use as a coking coal or even as a fraction of a coking coal blend. The low reactives content also reduces the liquefaction potential of the coal, as the optimum reactives content for a coal regarded as suitable for liquefaction should be in excess of 60% by volume (Cudmore, 1978).

Table 1 compares the desirable properties of coal suitable for liquefaction with the properties of Tasmanian Triassic coal.

As mentioned, the caking indices of the coal are poor. That is, crucible swelling number ranges from 0-1, Gray-King coke type B and Roga Index 0.

TABLE 1

Desirable Properties of Coal for Liquefaction	Tasmanian Triassic Coal
a) Vitrinite Reflectance < 0.80%	0.67%
b) H/C atomic ratio (d.a.f.) > 0.75	0.69
c) Vitrinite plus exinite content > 60%	19.0 %
d) Volatile Matter (d.a.f.) > 35%	31.7 %
e) Relatively low concentration of heteroatoms (Nitrogen, oxygen and sulphur).	Oxygen concentration relatively high.

(Extract of Table 12 Cudmore 1978)

The coal has a high inherent ash content which cannot be appreciably reduced by washing at low specific gravities. The ash content of the coal usually ranges from 18-22% (dry basis) after beneficiation in a washing plant. The high ash content of the coal and poor coking properties essentially restricts usage of the coal to steam raising or for use in cement manufacture. The high coal ash content also makes the coal unsuitable for the manufacture of char.

Analyses for coal seams within the licence area are restricted to those for the Merrywood Seam and seams intersected in Department of Mines drillhole DDH22.

The Merrywood Seam analyses are as follows :-

From Hills (1922) Sample No. 693 Beta Coal Bed (Merrywood Seam)

Description	Thickness (m)	
Yellowish grey fireclay	2.44	
COAL, dull to bright, hard	0.66	
Clay, yellowish - grey	0.05	Seam Thick.
COAL, dense, bright laminae	0.56	1.95 m
Clay, yellowish - grey	0.05	
COAL, dense hard	0.63	
Undetermined		

Sample No. 693 was obtained from the outcrop in Merrywood Creek and does not represent a complete section of the seam.

Proximate				Ultimate(?)					S.E.	
Moisture	V.M.	F.C.	Ash	S	H	C	O	N	MJ/kg	S.G.
2.66%	25.10	53.88	18.36	0.44	4.59	57.76	17.69	1.62	5.34	1.44

1945 Analyses

In 1945 analyses were made of three portions of the seam on either side of the two bands, representing the working section of the seam. A generalised log of the seam is given below :-

Coal and shale	0.61 m
Coal	1.63 m
Shale band	0.05 m
Coal	0.56 m
Shale band	0.05 m
Coal	0.33 m

Sample Position	Thick. (m)	Proximate					
		Moist. (105°C)	Ash	V.M.	F.C.	S	S.E. MK/kg
Top	1.22	2.40	20.00	26.66	50.94	0.35	26.05
Middle	0.53	1.92	19.54	28.20	50.34	0.36	26.21
Lower	0.28	1.82	12.28	31.60	54.30	0.34	29.28
Calc Av.	2.03	2.19	18.82	27.74	51.24	0.35	26.54

Proximate analyses for seams intersected in D.M. DDH22 are given below. The seams intersected in this hole appear

to be stratigraphically below the Merrywood Seam.

Roof Depth (m)	Floor Depth (m)	Thick. (m)	Recovery (m)	Moist (%)	Ash (%)	V.M. (%)	F.C. (%)	Specific Energy (MJ/kg)
79.28	79.83	0.55	0.46	3.6	23.4	31.3	41.6	24.7

10. COAL RESERVES

Calculation of coal reserves within the E.L. is not possible because of insufficient information being available on the continuity, extent and thickness of the seams. The absence of data and geological uncertainty is such that even estimation of reserves in the inferred category is in conflict with the parameters for the calculation of coal reserves recommended by various authorities.

A possible exception to the non-calculation of reserves is in a restricted area east and northeast of the old underground workings at Merrywood. The area lies between the old workings and the edge of the dolerite. Extension of the Merrywood seam under the dolerite is doubtful, because DDH18 located approximately 1000 metres north of the edge of the dolerite only intersected the lower 50 metres of the coal measures and is barren of coal. Therefore, reserves can only be calculated for an area which is approximately 500 X 400 m^2.

Indicated Reserves at Merrywood

Seam thickness = 2.74 m (effective working thickness)
S.G. of coal = 1.44
Area = 500 X 400 m^2
In situ raw coal = 500 X 400 X 2.74 X 1.44
= 789 120 tonnes
Say 790 000 tonnes

The pillars in the old Merrywood Mine also contain small reserves of coal. Some of the pillars could possibly be mined by open cut mining.

11. POTENTIAL

Surface mapping,coal outcrops and the four Department of Mines diamond drillholes within the licence have indicated that coal potential is restricted to the upper section of the coal measures in the St. Pauls River Valley - Royal George area. That is, the thicker potentially economic coal seams occur in the upper 150 - 200 metres section of the coal measures.

North of the St. Pauls River Valley surface mapping and three Department of Mines drillholes have indicated that the upper coal bearing section of the measures is not present.

The coal seams outcropping or intersected in drillholes within the area are less than 2.0 m thick, except for the seam at the old Merrywood Mine. Coal seams greater than 1.50 m thick within the area are as follows :-

Merrywood Seam - 3.38 m (effective working section 2.74 m)
Lewis Hill Prospect Tunnel - 1.83 m (Thickness as reported by Hills, 1922)
Prospect Adit Royal George - 1.83 m (Thickness as reported by Hills, 1922)
D.M. DDH22 'Lochaber' - 1.62 m (1.49 m recovered depth 155.19 - 156.81 m)

Additionally, a coal seam 2.87 m thick (of which 1.96 m is coal) outcrops in Coal Rivulet approximately 700 metres east of the E.L.

All of the seams in excess of 1.75 m thick occur within the upper 100 metres of the measures.

Four areas within the Royal George/St. Pauls River Valley appear to have some potential for limited open cut and underground coal reserves. However, the apparent lenticular nature and small areal extent of the coal seams could restrict exploitation to a number of very small mines, possibly only suitable for small operators.

The four potential areas are designated alphabetically A-D (See Plate 2 for locations) and are briefly discussed below.

Area A

This area extends from the old Merrywood Mine to the western margin of the licence. Some potential possibly exists for small open cuts if the Merrywood Coal Seam is present west of the old open cut. Coal fragments have been found in creek beds to the west of the old open cut. Area A conforms to the outcrop of the coal measures and does not appear to have any extension under the dolerite to the north or east. Dips of 10-15^{o} measured within the area reduce the potential of this area.

Area B

Area B is located on the eastern portion of the licence. A number of thin coals seams outcrop in the area. The thickest seam known to occur in Area B was intersected in D.M. DDH22 at a depth of 155.19 - 156.81 m. The indicated seam thickness was 1.62 m, although only 1.49 m of coal was recovered.

A banded coal seam 2.87 m thick also outcrops in Coal Rivulet, approximately 700 metres east of Area B, outside the E.L.

Potential for coal in this area appears to be restricted to the coal measure section lying above the collar level of hole D.M. DDH22. If coal seams with a mineable coal thickness exist in this section, then some potential for underground coal possibly occurs below the Little John - Mt. St. John Tier.

Area C

This area is located on the northern slopes of Lewis Hill. Two coal seams 0.88 m and 1.83 m (old prospect tunnel) thick outcrop in Rockhouse Creek. Some potential exists for limited open cut reserves with possible underground extensions under Lewis Hill if the 1.83 m thick seam is continuous and does not thin.

Area D

Area D is located south of Royal George and west of Area C. A prospect tunnel is reported to have opened a 1.83 m thick seam (Hills 1922). Drilling is required in this area to test the upper section of the coal measures for potential underground reserves.

12. RECOMMENDATIONS

That :-

- the upper 150-200 metres of the coal measures in each of the four areas A, B, C, D be drilled in order to determine the presence of coal seams with a thicknessand quality suitable for mining.

- initially one hole be drilled in each of the areas, with additional drillholes dependent on initial results.

- the holesbe fully cored diamond drillholes and that all core, especially coal core be logged in detail.

- coal seams greater than 0.50 metres thick be sampled and analysed.

- drilling operations be planned to commence in late October when surface conditions are expected to be drier and more suitable for vehicle access to the proposed drill sites.

13. CONCLUSIONS

Coal seams with possible economic potential appear to be restricted to the upper 150-200 metres or less of the Triassic Age coal measure section.

Four areas in the Royal George/St. Pauls River Valley portion of the E.L. appear to have some potential for coal. Exploratory drilling is required in each of these areas to determine the presence of economic coal seams.

There appears to be no potential for economic coal in the northern portion of the E.L., north of the St. Pauls River Valley.

Coal reserves can only be calculated for a small area near the old Merrywood Mine. Indicated in situ raw coal reserves are 790 000 tonnes. These reserves could possibly be increased slightly by open cut mining of some of the pillars in the old Merrywood Mine. In other portions of the E.L. insufficient information and geological uncertainty precludes calculation of reserves.

The coal within the licence is a low rank high volatile bituminous type. The coal is typically dull and has a low reactives (vitrinite + exinite) content. The coal is unsuitable for coking making or blending because of its poor caking indices and low reactives content. The high ash content of 18-22% for washed coal restricts possible use to steam raising and cement manufacture. Conversion potential for the coal also appears to be low.
