SUMMARY

A gradient array reconnaissance survey carried out over the Dobsons Creek area has defined three formations each with distinct characteristics. A marked divergence in the strikes of the central and eastern formations suggests the presence of a strike fault.

A number of significant induced polarization anomalies were defined which have been recommended for 100 feet and 200 feet dipole-dipole detail to assist in their evaluation. A number of the responses defined are considered to be due to massive shale and/or sulphide sources of coarse grain, and as such are of primary geophysical interest.
