R832ROSSARDEN SLIME TAILINGS RETREATMENTIntroduction

Mr. H. Staepoole submitted two samples from tailings dams at Rossarden with a view to assessing tin and tungsten recovery from retreating this material.

The samples submitted were:-

830790 from Dam 1

830791 " Dam 2

As a preliminary assessment a sizing and distribution of tin and tungsten has been done on both samples.

Results

The results of these sizing tests are:-

830790: Dam 1

| Fraction (μm) | Mass (%) | | Assay (%) | | Distribution (%) | | | |

C/S Temperature 15°C.

Discussion

In order to assess possible recovery these two sizing analyses will be considered in three size ranges, namely:-

1. The plus 600 μm material which is considered too coarse for retreatment and contains insufficient values for regrinding can be excluded from further consideration.
2. The material passing 600 μm but retained in C/S2 can be considered that most likely to be recovered in retreatment and should be a reasonable guide to what can be achieved by a gravity recovery circuit such as is envisaged, and
3. The slime material, C/S3 and finer, may be worth concentrating although recovery from slime material cannot be expected to be very high in a gravity circuit.

- 3 -

Applying the above to the results we have:-

830790 Dam 1

1. The coarse reject, -9.53mm; + 600 μ m, contains:-
 Mass 5%; Tin 1%; Tungsten 1%.
 and Assays 0.08% Sn; 0.06% WO₃
2. The main fraction for retreatment, -600 μ m to C/S2 contains:-
 Mass 35%; Tin 34%; Tungsten 36%.
 and Assays 0.4% Sn; 0.4% WO₃.
3. The slime fraction, C/S3 and lower, contains:-
 Mass 60%; Tin 65%; Tungsten 63%.
 and Assays 0.5% Sn; 0.4% WO₃.

830791 Dam 2

1. The coarse reject, -19.05mm; + 600 μ m, contains:-
 Mass 17%; Tin 5%; Tungsten 2%.
 and Assays 0.1% Sn; 0.06% WO₃.
2. The main fraction for retreatment, -600 μ m to C/S2 contains:-
 Mass 51%; Tin 58%; Tungsten 52%.
 and Assays 0.5% Sn; 0.5% WO₃.
3. The slime fraction, C/S3 and finer, contains:-
 Mass 32%; Tin 37%; Tungsten 46%.
 and Assays 0.5% Sn; 0.7% WO₃.

Thus it can be seen that from 830790 about a third of the tin and tungsten are contained in what can be regarded as a recoverable fraction. Not all of this would be recovered in practice but some could be recovered from the slime material so that as a preliminary guide a recovery in a low grade tin product of say one third of the values seems at this stage a reasonable estimate.

With 830791 the prospects look better with the possible recovery of half the values in a low grade product.

The nature of the tin and tungsten occurrence can be gauged from the close relationship between the distribution of mass and values in the fractions of interest above. This suggests a fairly uniform distribution of the values indicating a uniform composition in the grains of the various sizes although in both C/S1 fractions, where density becomes a factor in the sizing, there is a tin concentration indicating some non uniformity of grain composition. However to achieve a marketable concentrate

003

(say 50% Sn) any retreatment would have to include grinding of the low grade concentrate followed by further concentration and magnetic separation of the wolfram.

A closer study of the results for 830791 shows that the fractions +38 μ m, C/S1 and C/S2 together contain 15% of the mass, 45% of the tin and 46% of the wolfram and would assay 1.2% Sn and 1.5% WO₃. If this material could be separated by hydraulic cyclones it offers a reasonably high grade gravity feed containing just under half the values.

Conclusion

There would appear to be better prospects for retreating 830791, Dam 2 with a recovery of around half the values in a low grade concentrate which would have to be further ground and concentrated, with losses, to achieve market products.

R829

TIN AND TUNGSTEN DISTRIBUTION IN COARSE TAILINGS FROM THE
 ABERFOYLE MINE AT ROSSARDEN AND A RECOVERY TEST INCORPORATING
 GRINDING OF A SELECTED SIZE RANGE OF THE TAILINGS.

Introduction

Research project R827 examined grab samples from the face from several locations around the coarse tailings dump at Rossarden.

The samples in this investigation were derived by drilling the tailings dump from top to bottom at selected localities. Holes 2 and 3 were reported to be very successful holes in which sample recovery was maintained from the top to the bottom of the hole. The remaining holes were ~~less successful as sample recovery was not so good.~~ The samples from these latter holes were bulked to provide the feed for rod milling and a recovery test.

The details of the samples which were submitted by Mr. H. Stacpole are as follows:-

| <u>Registered Number</u> | <u>Description</u> |
|--------------------------|---|
| 821925 | Hole 2 |
| 821926 | Hole 3 |
| 821927 | { Hole 1, Hole 4, Hole 5, Bag 6, Bag 7, Hole 8 (top Hole 8, 8.5-15, Hole 9, Hole 10-11 metre |

Tin and WO₃ Distributions

Samples 821925 (Hole 2) and 821926 (Hole 3) were screened and the size fractions were assayed for tin (Sn) and tungstic oxide (WO₃).

The sizings and distribution of Sn and WO₃ were as follows:-

005

Reg. No 821925 Hole 2.

| + 3.35 mm | 9.3 | 73.9 | 0.11 | 0.01 | 9.2 | 50.9 | 4.2 | 45.8 |
| + 2.8 mm | 6.8 | 80.7 | 0.06 | 0.02 | 3.9 | 54.8 | 3.8 | 49.6 |
| + 2.36 mm | 4.8 | 85.5 | 0.13 | 0.08 | 5.5 | 60.3 | 13.6 | 63.2 |
| + 1.4 mm | 9.5 | 95.0 | 0.23 | 0.06 | 20.0 | 80.3 | 20.7 | 83.9 |
| - 1.4 mm | 5.0 | 100.0 | 0.43 | 0.09 | 19.7 | 100.0 | 16.1 | 100.0 |
| Calc. Head | 100.0 | | (0.11) | (0.03) | 100.0 | | 100.0 | |

These results show that it would be desirable to screen the material on 5.6 mm to produce a coarse product for paving use, since the -5.6mm + 4.75mm fraction carries a considerable quantity of tin. Removal of the oversize material lifts the grade of the undersize material as follows:-

| -5.6 mm | % Mass | Assay % | | % Recovery | |
|---------|--------|---------|-----------------|------------|-----------------|
| | | Sn | WO ₃ | Sn | WO ₃ |
| Hole 2 | 65.5 | (0.15) | (0.03) | 89.9 | 85.6 |
| Hole 3 | 52.6 | (0.17) | (0.04) | 80.3 | 77.9 |

Inserting a 2.36 mm screen would give two products as follows:-

| | <u>% Mass</u> | <u>Assay %</u> | | <u>% Distribution</u> | |
|-----------------|---------------|----------------|-----------------------|-----------------------|-----------------------|
| | | <u>Sn</u> | <u>WO₃</u> | <u>Sn</u> | <u>WO₃</u> |
| <u>Hole 2</u> | | | | | |
| -5.6mm + 2.36mm | 43.8 | (0.08) | (0.02) | 33.3 | 31.3 |
| -2.36mm | 21.7 | (0.28) | (0.06) | 56.6 | 54.3 |
| <u>Hole 3</u> | | | | | |
| -5.6mm + 2.36mm | 38.1 | (0.12) | (0.03) | 40.6 | 41.1 |
| -2.36mm | 14.5 | (0.30) | (0.07) | 39.7 | 36.8 |

Inserting a 1.4 mm screen would give two products as follows:-

| | <u>% Mass</u> | <u>Assay %</u> | | <u>% Distribution</u> | |
|----------------|---------------|----------------|-----------------------|-----------------------|-----------------------|
| | | <u>Sn</u> | <u>WO₃</u> | <u>Sn</u> | <u>WO₃</u> |
| <u>Hole 2</u> | | | | | |
| -5.6mm + 1.4mm | 57.7 | (0.10) | (0.02) | 51.7 | 54.9 |
| -1.4mm | 7.8 | 0.53 | 0.10 | 38.2 | 30.7 |
| <u>Hole 3</u> | | | | | |
| -5.6mm + 1.4mm | 47.6 | (0.16) | (0.04) | 60.6 | 61.8 |
| -1.4mm | 5.0 | 0.43 | 0.09 | 19.7 | 16.1 |

Recovery Test

The composite sample, Reg. No 821927 was wet screened on a 0.457 m. dia. Sweco screen fitted with a 4.75 mm and a 1.24 mm screen cloths. The -1.24 mm product was pumped to a Vickers 5 turn CC series spiral.

The spiral concentrate was sized by hand screening using 200 mm dia. laboratory test screens with 500µm and 250µm apertures. The +500µm fraction was further concentrated in the 60mm X 40mm Denver jig. This concentrate was magnetically separated with the dry Rapid high intensity magnetic separator and the non-magnetics were further concentrated by panning. Sulphides were skin floated out during the panning operation.

The -500µm + 250µm fraction was concentrated on the Deister table and the concentrate was further concentrated by panning and sulphides were removed by skin flotation during panning. The pan concentrate was magnetically separated with the dry Rapid high intensity magnetic separator.

The -250 μ m fraction was concentrated on the Deister table, and the table concentrate was subjected to low intensity magnetic separation using a hand magnet to remove highly magnetic material, possibly ferro-silicon. The non-magnetics were then floated in a flotation cell to remove sulphides. The flotation tail was further upgraded by panning and the pan concentrate was magnetically separated using the dry Rapid high intensity magnetic separator.

The results of this part of the recovery test were as follows:-

Spiral Concentrate

Because of the poor recovery of tin and tungsten in the +500 μ m fraction, it was decided to retreat the spiral tailing.

The spiral tailing was wet screened by hand using 200mm dia. laboratory test screens with 500 μ m and 125 μ m apertures.

The +500 μ m fraction and the -500 μ m + 125 μ m fractions were concentrated by panning. The pan concentrate in each case was magnetically separated using the dry Rapid high intensity magnetic separator. The -125 μ m fraction was table concentrated using the Deister table to give a concentrate T1C and a tailing T1T. The concentrate was retabled to give a concentrate T2C and a tailing T2T. This table concentrate T2C was magnetically separated with a low intensity hand magnet to remove highly magnetic material. The non-magnetics were then floated in a flotation cell to remove sulphides. The flotation tail was magnetically separated with the dry Rapid high intensity magnetic separator, and the non-magnetics were panned to produce a final concentrate.

The results of this retreatment of the spiral tailing were as follows:-

Spiral Tailing

The distribution in the two sets of results from the recovery test reported so far relate to the tin and tungsten in the original feed.

The actual recovery performance of the spiral in the -1.24mm +500µm size range in a final product was only 13.6% for tin and 23.5% for tungsten. A further 48.9% of the tin and 40.4% of the tungsten was recovered by panning this size fraction in the spiral tailing to give final concentrates.

The spiral did much better in the size ranges finer than 500µm. The actual recovery performance of the spiral in the size ranges finer than 500µm was 58.6% for tin and 52.4% for tungsten. Retreatment of these size fractions in the spiral tailing recovered a further 4.7% of the tin and 5.2% of the tungsten.

The -4.75mm + 1.24mm fraction of the original feed was ground in the 0.31m. dia. X 1.0m Denver rod mill in closed circuit with the 0.457m. dia. Sweco screen fitted with a 1.24mm screen cloth.

The screen undersize was concentrated with the 150mm X 100mm Denver jig. The jig concentrate was hand screened using 200mm. dia. laboratory test screens with 500µm and 125µm apertures.

009

The +500 μ m size fraction was then further concentrated using the 60mm X 40mm Denver jig. The jig concentrate and the jig bed were panned. A sulphide concentrate was removed by skin flotation. The pan concentrate was magnetically separated with the dry Rapid high intensity magnetic separator. The first three magnetic products were bulked for a wolfram concentrate and the fourth magnetic product was put with the non-magnetics to give a tin concentrate.

The -500 μ m + 125 μ m fraction was tabled to produce a concentrate and a tailing. The table concentrate was panned. The pan concentrate was skin floated to remove sulphides, and then was magnetically separated. The first three magnetic products were bulked for a wolfram concentrate and the fourth magnetic product was put with the non-magnetics to give a tin concentrate.

The -125 μ m fraction was floated in a flotation cell to remove sulphides. The flotation tail was panned, and the pan concentrate was magnetically separated. The first three magnetic products were bulked for a wolfram concentrate, and the fourth magnetic product was put with the non-magnetics for a tin concentrate.

The results of cleaning the jig concentrate are as follows:-

| <u>Product</u> | <u>Mass</u> <u>g</u> | <u>Assay %</u> | | <u>% Distribution</u> | |

Because of the poor recovery of tin and tungsten in the -125 μ m fraction, it was decided to retreat the jig tailing. The jig tailing was screened on the 0.457 m. dia. Sweco screen fitted with a 152 μ m screen cloth. The +152 μ m material was not further treated. The -152 μ m material was concentrated on the Deister table. The table concentrate was floated in the flotation cell to remove sulphides, and the flotation tailing was magnetically separated.

010

The third and fourth magnetic products and the non-magnetics were individually panned. The panned tails from each were combined with the first two magnetic products.

The results of the retreatment of the jig tailings were as follows:-

| <u>Product</u> | <u>Mass</u> g | <u>Assay %</u> | | <u>% Distribution</u> | |
|-------------------|------------------|----------------|-----------------------|-----------------------|-----------------------|
| | | <u>Sn</u> | <u>WO₃</u> | <u>Sn</u> | <u>WO₃</u> |
| J1T + 152 μ m | 15.562 | 0.05 | 0.02 | 7.2 | 5.2 |

Retreatment of the -152 μ m fraction of the jig tailings increased the overall tin recovery from the grinding of the -4.75mm + 1.24mm fraction of the original feed from 37.2% to 45.2%. The wolfram recovery was increased from 43.0% to 52.7%.

A summary of the whole operation is as follows:-

| <u>Product</u> | <u>Mass</u> g | <u>Assay %</u> | | <u>% Distribution</u> | |
|----------------------------|------------------|----------------|-----------------------|-----------------------|-----------------------|
| | | <u>Sn</u> | <u>WO₃</u> | <u>Sn</u> | <u>WO₃</u> |
| +4.75mm | 55.93 | 0.07 | 0.03 | 37.0 | 36.0 |
| -4.75mm + 1.24mm Tin Conc. | 0.03 | (62.5) | | 19.3 | |
| WO ₃ Conc. | 0.02 | | (45.6) | | 20.7 |
| Combined Other Products | 34.61 | (0.07) | (0.02) | 23.4 | 18.7 |
| -1.24mm Tin Conc. | 0.02 | (67.8) | | 12.8 | |
| WO ₃ Conc. | 0.01 | | (50.0) | | 13.7 |
| Combined Other Products | 9.38 | (0.08) | (0.05) | 7.5 | 10.9 |
| | 100.00 | | | 100.0 | 100.0 |

Disregarding the tin and tungsten in the +4.75mm fraction which is destined for sale as paving material, then the recoveries in each operation and the total recovery from the material that was treated is summarised as follows:-

| | <u>Recovery</u> | |
|-----------------------------|-----------------|-----------------------|
| | <u>Sn</u> | <u>WO₃</u> |
| -4.75mm + 1.24mm rod milled | 45.2 | 52.5 |
| -1.24mm fines treatment | 63.1 | 55.7 |
| Overall | 51.0 | 53.8 |

011

Discussion

Examination of the tin and tungsten distributions in Holes 2 and 3 suggest that the rod mill feed should be -5.6mm instead of 4.75mm, as in both of these holes a considerable quantity of tin appears in the -5.6mm + 4.75mm fraction. Unfortunately this size fraction could not be included in the rod milling recovery test because there was no 5.6mm screen cloth to fit the Sweco screen. The tin and tungsten distributions also suggest a further variation from the size range used to feed the rod mill in the recovery test, and that is that the lower size of the rod mill feed be lifted to about 2.0mm, and thus increase the size range of the material for fines treatment.

Neither the spiral or the jig proved to be satisfactory as a rougher concentrator of the -1.24mm material. The spiral lost significant quantities of tin and wolfram in the coarse end of the size range, and the jig lost significant quantities of tin and wolfram in the fine end of the size range.

Probably if the -2.0mm material was screened on about 300µm, and the +300µm material was fed to a jig and the -300µm material was fed to spirals, the best recovery would be obtained in rougher concentration.

Conclusions

After screening coarse tailings from the old Aberfoyle Mine at Rossarden on a 4.75mm screen, 51% of the tin and 53% of the wolfram in the undersize can be recovered at a saleable grade.

The recovery obtained by rod milling the -4.75mm + 1.24mm fraction was 45% of the tin and 52% of the wolfram.

The recovery obtained by treatment of the -1.24mm fraction was 63% of the tin and 55% of the wolfram.
