

7. CONCLUSIONS AND RECOMMENDATIONS

- A follow-up sampling programme, involving locations where relatively interesting base metal assay values were previously detected failed to identify any significant surface anomalies.
- A SIROTEM survey, conducted to test the entire area of RGCE's Mt. Jacob grid, offered no encouragement for potential VMS type deposits of a size, depth, orientation and conductivity that could be expected to respond to the survey.
- In view of the above results and due to better prospects within other tenement holdings, it is recommended that the area covered by E.L. 8/88 - Lorinna be relinquished. However, our decision to do this does not negate the areas future prospectivity.
