ANNUAL TECHNICAL REPORT ON EL 12/93

Title	:	Final Technical Report, EL 12/93 Scamander River Prospect October 1998
Tenement	:	EL 12/93 MPI Gold Pty Ltd 1 Walker Avenue WEST PERTH WA 6005
Commodities	:	Gold, Base Metals
Key Words	:	Gold, Exploration, BLEG Geochemistry Geological Mapping, Diamond Drilling

SUMMARY

This report details exploration activities undertaken by MPI Gold Pty Ltd (MPI) on EL 12/93 for the five year period from 12th November 1993 to the 12th of November 1998.

The Scamander River Prospect was originally acquired to explore for mesothermal gold mineralisation associated with quartz veins in the Mathinna Beds sedimentary package.

Exploration involved BLEG stream sediment geochemistry followed by rock-chip sampling and soil sampling of individual prospects. The Golden Ridge prospect produced encouraging results from an area of previous costeans and limited drilling carried out by Billiton Australia in 1991/92. MPI carried out several programmes of diamond drilling at Golden Ridge, totalling 10 diamond drillholes, which encountered encouraging mineralisation associated with a steeply dipping fracture / quartz vein system in shallow dipping turbidites.

1. INTRODUCTION

This report details exploration activities undertaken by MPI Gold Pty Ltd (MPI) on EL 12/93 Golden Ridge Project during the five year period from 12 November 1993 to Relinquishment of the property in October 1998.

The Scamander River EL 12/93 is located in northeastern Tasmania, 20km west of St. Helens and 70 km east of Launceston (Figure 1). The tenement was granted to MPI on 12 November 1993.

Exploration consisting of geochemical stream sediment and soil sampling, rockchip sampling and diamond drilling was carried out over a five year period. Approximately $550,000 was expended by MPI, mostly concentrated at the Golden Ridge Prospect where several significant diamond drilling intercepts were obtained.

2. REGIONAL GEOLOGY AND EXPLORATION MODELS

The Scamander Exploration Licence E12/93 was acquired over an area of Siluro-Devonian Mathinna Beds turbidites along the southern margin of the Devonian Blue Tier granite batholith.

The Blue Tier Batholith is one of three large batholiths in eastern Tasmania which together cover 2500 square km (Burrett and Martin 1989). Emplacement of the Devonian batholiths is interpreted to have been at a high level due to narrow contact aureoles and the presence of the St Mary's porphyrite – an extrusive equivalent of these granites (Taylor and Rendell 1991).

A spatial and possible genetic relationship has been postulated between the granitoids and mineralisation in northeast Tasmania. Three styles of mineralisation are present :

i) Orogenic gold-vein style deposits – eg Mathinna , Tasmania

ii) Tin,Tungsten vein mineralisation – eg Aberfoyle, Great Pyramid

iii) Granite greisen tin mineralisation – eg Anchor, Royal George

The main gold trend in northeast Tasmania is the Mangana-Mathinna-Alberton trend, a northeast trending structural corridor over 40km long which has produced over 0.5 million ounces of gold. The Brilliant Creek Goldfield, located within EL 12/93, lies to the east of this trend closer to the margin of the geochemically distinctive Blue Tier Batholith (Randell, 1991).

3. PREVIOUS EXPLORATION

Within the area covered by EL12/93 an initial phase of gold prospecting and mining occurred at the turn of the century with a second phase in the 1930's. Only minor production resulted and was primarily small test parcels of ore. This activity is reported on as the Hogans Track and the Brilliant Creek Goldfield in the following old series Mines Department reports;

"Report on the Queen of the Earth Gold Mine and neighbourhood" by WH Twelvetrees, 1900.

"Report on Gold Mines near Hogans Track" by WH Twelvetrees, 1899.

"Notes on the Trafalgar Leases - Upper Scamander District" by QJ Henderson, 1935.

"Report on the Geological Survey of the Country between Scamander and Mathinna" by QJ Henderson, 1935.

Unnamed report by QJ Henderson, 1935.

EL 12/93 has been held under licence in part or in it's entirety by Oceania Tasmania (EL 24/82), Union Corporation (Aust) Pty Ltd (EL 21/80), Texins Development Pty Ltd and Aureole NL et al in joint venture with Billiton Australia (EL 58/88). These companies targeted gold with the exception of Union Corp whose primary target was base metals. With the exception of Billiton's exploration all work has been of a regional nature.

Billiton's programme included stream and soil geochemistry, mapping and costeaning. The programme culminating in the drilling of 7RCP holes at the Golden Ridge and Trafalgar prospects, the best intersection 6m @ 4.41 g/t Au in RCP3 at Golden Ridge. The drilling programme was not completely effective due to drilling problems below the water table and holes at the Trafalgar prospect were drilled parallel to the strike of the mineralised veins.

Geological consultants were used as part of Billiton's programme, which included;

- a regional study of gold mineralisation and potential in NE Tasmania by Taylor see Appendix 3 Randell Dec 1991. Taylor's conclusions were that the Devonian batholiths associated with gold mineralisation in NE Tasmania were emplaced at relatively high levels in the crust, developing narrow aureoles and limited gold potential.

- a study of the structural setting, mineralisation styles, geophysical properties of the main rock units and the lithogeochemistry of granitoids in the licence was completed by Davidson and Roach see Appendix 2 Randell Feb' 1991.

In addition two honours projects were completed which are relevant to exploration at Golden Ridge, these are by;

- Taylor 1992, a structural traverse across the Mathinna Group mainly east between Golden Ridge and the east coast.

- Capp 1992, structure, lithogeochemistry and controls on gold mineralisation at Evercreech and Golden Ridge. A summary of the thesis is included in Randell March 1992.

4. EXPLORATION COMPLETED BY MPI

4.1 BLEG Geochemistry

The Billiton stream sediment sampling survey (Randell 1991) was extended and infilled. Additional sampling was carried out in the headwaters of the Scamander and Avenue Rivers and Brilliant Creek. Active stream sediment was collected and separated into a –80# fraction for multi-element geochemistry and a –16# fraction for Cyanide leach (BLEG) at Analabs, Burnie.

Anomalous results have been plotted at 1:25,000 scale, with the Billiton samples also shown (Figure 2).

Appendix 1 contains analytical results.

4.2 Surveying

East Coast Surveying of St Helens were contracted to install a 50m x 50m to 50m x 25m grid over the Golden Ridge prospect. All pegs are labeled with AMG eastings and northings, and a relative level (RL). A contour plan was also generated.

The topographic contour plan of the Golden Ridge prospect is shown as Figure 3.

4.3 Geological Mapping

At Golden Ridge compilation of existing data and additional geological mapping at 1:1000 scale was carried out in order to define controls on mineralisation at the prospect and define drilling targets.

The data compilation and fact geology is shown on Figure 4.

4.4 Soils and Rockchip Geochemistry

Previous soil sampling at Golden Ridge by Billiton was re-plotted. Figure 4 shows simplified soil contours.

Additional soil sampling to follow up BLEG anomalies was carried out at Risky Ridge and in the headwaters of the Queen of the Earth Creek. Samples were collected from the B horizon on 50m spaced centres. A total of 105 samples were collected with the –80# fraction submitted to Analabs, Burnie for Au, Cu, Pb, Zn and As analysis.

Soil sample locations are shown on Figure 2.

Soil sample results are contained in Appendix 1.

Rockchip sampling was carried out at Golden Ridge and the Double Event prospect.

Rockchip sample locations are shown on Figures 2 and 4.

Rockchip sample results are contained in appendix 1.

4.5 Drilling

Several programmes of diamond drilling were carried out at the Golden Ridge prospect. Diamond drilling was initially designed to test a north-east trending fracture/quartz stock work system which had been previously worked as the Brilliant and New Golden Ridge workings, and has been the subject of geochemical sampling and RC drilling by Billiton (Shell Metals) (Figures 2 and 3). The previous work by Billiton produced wide, low grade costean results (eg 34.5m @ 1.37 g Au/t) and some RC drilling intersections which MPI considered may be indicative of a high level quartz vein stockwork which may develop into a higher grade sheeted vein system overlying granite at depth.

Ten diamond drill holes have been completed by MPI under the main areas of workings at New Golden Ridge and Brilliant, for a total of 2125m.

NQ diamond drill core was split on site and submitted to Analabs, Burnie for Au by fire assay and Cu, Pb, Zn, As analysis. Some anomalous samples were re-submitted for W, Bi, Sb, Te, Mo, Ba, Ag analysis.

Figure 5 shows diamond drillhole locations and a surface projection of assay results.

Figures 6 i) to 6 v) show cross sections through the MPI and previous Billiton drilling.

4.6 Petrography

A total of three samples were submitted from drillhole GRD 2 for mineragraphic / petrographic description. Samples from 75.6m, 77.3m and 78.6m were submitted.

Mineragraphic / petrographic descriptions are contained in the 1995 Annual Technical Report - Dugdale, 1995.

5. INTERPRETATION OF RESULTS

5.1 Regional Geochemistry

Regional stream sediment sampling identified several anomalies, the strongest of which are developed in Brilliant Creek. Peak results of 98.2 ppb Au, 88.90 ppb Au and 54.4 ppb Au are related to dispersion of gold mineralisation from Golden Ridge. Workings at Brilliant and New Golden Ridge may have contributed some contamination to the Creek, however veining is evident along the ridge well beyond the workings, indicating that the ridge may coincide with a silicified fault zone.

Follow up soil sampling at Queen of the Earth Creek detected a 400m wide weakly anomalous zone of 14 to 40ppb Au and up to 210 ppm As. This zone coincides with a sheared and slightly limonitic siltstones from which rockchip samples assayed upto 0.50 g Au/t.

At Risky Ridge results from 4 NNE trending traverses produced results of upto 32 ppb Au and 32.5 ppm As. These are weak anomalies, which did not justify further work.

5.2 Geology

Geological mapping was carried out over the Golden Ridge prospect.

Mineralisation at Golden Ridge is interpreted to occur in a moderate to steeply dipping fracture/shear zone within a shallowly dipping hornfelsed / siltstone - sandstone sequence. The zone has an exposed strike length of 180m and a maximum width of 35m at surface. Mineralisation is best developed in the siltstone dominated sequence as limonite – quartz veinlets and fractures. The fracture zone is interpreted to trend east-northeast west-southwest and is intersected by a series of discrete north-south trending faults.

Veins of two main orientations are developed – the dominant trend at approximately 040° magnetic and a 130° trending set of laminated veins. The main mineralisation is associated with a shallow northeasterly plunging anticline capped by a relatively massive overlying sandstone unit, which has well developed but discontinuous quartz reefs upto 1m wide, with little wallrock alteration.

5.3 Drilling

The Golden Ridge prospect has been drilled on five transform sections spaced 40m apart on a northeast trending vein / fracture system. The Golden Ridge vein / fracture system includes veins oriented at 40° and 130° (magnetic) , developed as a conjugate set, within an envelope trending approximately 60°. The mineralisation dips vertically within shallow dipping sandstone and siltstone layers.

Initial drilling by Billiton (RCGR 1 to 4) tested a "blank" zone between two sets of workings at Brilliant stope and the New Golden Ridge. Intitial drilling by MPI consisted of two holes targeting mineralisation down dip from these workings and encouraging costean results. GRD 2 intersected encouraging mineralisation from 72m to 85m down hole associated with a series of parallel quartz-carbonate laminated veins and silicified breccias. The veins are <1cm to 15cm thick and associated with fine arsenopyrite with accesory galena, sphalerite and fine visible gold. Encouraging results from GRD 2 including 15m @ 2.22 g Au/t from 24m and 15.9m @ 1.37 g Au/t from 74m warranted additional drilling.

Follow up drilling of GRD 3 to GRD 6 produced generally patchy results with the exception of GRD 6 which intersected high grade veining at depth and to the east of the Brilliant stope, associated with a "blind" vein zone. An intersection of 4m @ 20.04 g Au/t from 231m was recorded, associated with lenticular quartz-carbonate veins with arsenopyrite, galena-sphalerite and specks of visible gold.

Further drilling of GRD 7 to 10 tested the mineralisation up and down dip from this high-grade mineralisation intersected by GRD 6, and also 40m to the northeast and southwest. Interpretation of results from this section suggests an en-echelon arrangement of mineralised zones within an easterly dipping enveloping surface. The enveloping surface appears to be marked by late brittle faults, which truncate the mineralisation.

GRD 7 was drilled to test the high grade zone 40m up dip from its intersection in GRD 6. A zone of narrow quartz veins and bleaching from 128.5m to 133.5m and a carbonate breccia/vein zone from 146m to 152m appear to correlate with the up dip extrapolation of the high grade lode intersected in GRD6. Isolated specks of visible gold were observed in some narrow veins. A weak zone of thin quartz veining was intersected from 170.5 to 200m down hole.

GRD 8 was drilled to intersect the eastern zone 40m up dip from GRD 7. Two zones of thin quartz veins with isolated specks of visible gold were intersected from 108m to 125m and from 125m to 135m.

GRD 9 was designed to test the high grade eastern zone 40m to the south of the GRD 6 section. Mineralisation was intersected from 150m down hole and became more strongly developed down the hole. From 290m to 320m numerous fine veins, bleaching and two intensely veined and sulphidised zones were intersected. The intensely veined zones from 295m to 298m and 319.5m to 321m both include >50% quartz–carbonate veins with abundant galena, sphalerite and arsenopyrite and trace visible gold and appear similar to the style of intense veining noted in the high grade zone of GRD 6. Results of upto 20.5 g Au/t have been produced from this hole, indicating that the system is open down plunge to the southwest.

GRD10, the deepest hole at Golden Ridge, intersected 5m @ 7.80 g Au/t from 201m including 1m @ 29.2 g Au/t close to the high grade intercept in GRD 6.

		1m @ 20.50 g Au/t from 319m
		4m @ 1.09 g Au/t from 325m
		1m @ 5.46 g Au/t from 336m
		Total 33m @ 1.35 g Au/t from 297m

6. CONCLUSIONS AND RECOMMENDATIONS

Regional geochemistry and field mapping indicates that the Golden Ridge prospect offers the greatest exploration potential on the Scamander River Exploration Licence.

The mineralisation intersected at Golden Ridge shows characteristics indicative of high level fracturing adjacent to the margin of the Devonian Bluer Tier granite batholith. Mineralisation is associated with steeply dipping veins in a broad anticline of siltstone – sandstone layers.

Several encouraging intersections were recorded from Golden Ridge, including several from non-outcropping blind zones to the east of the main workings. The system shows poor continuity, however indications of an en-echelon arrangement of veined zones, plunging to the southwest opens up potential in this direction.

Remaining exploration potential at Golden Ridge is evident in to key areas :

i) Shallow open pit potential for low grade fracture / stockwork mineralisation grading >1.5 g Au/t over 30m true width.

ii) Deeper high grade pods of mineralisation within a southwest plunging envelope on steeply dipping veins grading > 10 g Au/t.

MPI has relinquished the E.L. due to a perceived lack of size potential and continuity of mineralisation at Golden Ridge.
