Fax: (03) 6394 3435

15 March, 1998

SUMMARY

Exploration on EL 43/92 during the year was confined to the drilling of one (1) 250 m cored hole, designed to test both the depth extension of the North Cuni deposit and a large geochemical-magnetic anomaly west of the North Cuni Mine.

Results were disappointing. However, further drill testing has been recommended.

A full report on this drilling program is presented in the following report, attached as an appendix to this report:

> "*EL 43/92 Melba Flats (Cuni) Project, Western Tasmania. Report on Drill Hole Completed October 1998*" by L A Newnham, 28 December 1998.

1. SUMMARY

Previous drilling in the North Cuni-Genets Winze area at Melba Flats, north of Zeehan, had intersected a number of narrow zones of high grade Cu and Ni sulfide mineralisation associated with a series of gabbroic dykes or sills within a sequence of Cambrian sediments.

Drill hole MF10 was drilled to test two targets:

(i) the down-dip extension of the North Cuni massive Cu-Ni sulfide mineralisation

(ii) a previously untested magnetic and geochemical anomaly lying west of the North Cuni mineralisation

Gabbro dykes which correlated with the down-dip extension of the North Cuni dykes were intersected but no mineralisation was associated with them.

A deeper series of gabbroic dykes was also intersected to the west of the North Cuni dykes and these are interpreted as the source of the western magnetic-geochemical anomaly. No significant mineralisation was associated with these dykes.

Whilst results of this hole are disappointing, they are interpreted as highlighting the poddy nature of the massive sulfide lenses in this area, and should not represent a discouragement to further drilling. Down-hole EM on MF 10 may detect massive sulfide lenses adjacent to the hole as a guide to further drilling in this area.

2. LAND TENURE and ACCESS

EL 43/92 of nine square kilometres lies 10 kilometres north-east of Zeehan, midway between Zeehan and Renison Bell.

The licence is explored under a joint venture agreement between Allegiance Mining NL and Rio Tinto Exploration Pty Limited. Allegiance is currently the project manager and is incurring all expenditure.

The area is currently classified as Crown Land-Deferred Forest. However, following the recent signing of the Tasmanian Regional Forest Agreement, it is anticipated that the area will be re-classified as Crown Land-Multiple Use State Forest.

Access to the general area is via the Murchison State Highway which clips the south east corner of the licence. The licence area is essentially bisected by a major N-S 4-W-D track constructed early in the century to service mines in the area.

The Emu Bay railway currently terminates at the Melba Flats concentrates depot to the immediate east of EL 43/92.

This railway originally extended through the southern section of the licence area, joining with the North-East Dundas Tram.

3. GEOLOGY and PREVIOUS EXPLORATION

3.1 Geology:

The Melba Flats area is underlain by a sequence of Cambrian sediments (mudstones, siltstones, sandstones, volcaniclastic lithicwackes) intruded by a series of long, narrow gabbroic dykes or sills. The stratigraphy generally strikes N-S and dips east at approximately 60°. However, the northern section, near Genets Winze strikes north-east and dips south-east. Similarly, the southern section near the Nickel Reward Mine also strikes north-east.

The geology is shown on Fig 2 which is a reproduced 1:10,000 CRA plan, slightly modified by this writer, to highlight the extent of the gabbroic dykes.

Drilling and mining to date suggests there are a number of parallel gabbroic dykes, probably disrupted by cross faulting, especially in the vicinity of fold axes near Genets Winze and Nickel Reward.

Small lenses of nickel and copper sulfide mineralisation have been developed within these gabbro bodies intermittently over four kilometres of strike length.

Drilling suggests these sulfide lenses are up to 75 m long, but generally 0.5-5.0 m thick. Previous mining and drilling suggests they may have limited depth extents but this is open to substantial debate.

Nickel and copper mineralisation within these lenses can be high grade, commonly exceeding 15% combined Ni and Cu. Recent drilling has also confirmed elevated levels of Au, Pt, Pd within the sulfides.

3.2 History:

Comprehensive historical overviews have been present in other well documented reports.

In summary, copper and nickel sulfides were discovered at Melba flats in 1893 and have been intermittently worked by a series of shallow mines along a four kilometre strike length up until the late 1940s.

An estimated 8,000 t 7-11% Ni, 4-14% Cu were extracted from these workings.

Approximately 66 drill holes have been drilled into the area since the beginning of the century, but most of these were very shallow and records are typically poor. Very little drilling below 50 m vertical depth has been completed.

During the life of EL 43/92, the following work, in chronological order, has been completed:

- fixed wing TEM (QUESTEM) survey
- data review
- mineralogical studies on old drill cores
- whole rock regional geochemical surveys
- line cutting and gridding
- PROTEM and ground magnetic surveys over North Cuni-Genets Winze and Nickel Reward-Vaudeau area.
- core drilling five holes at North Cuni-Genets Winze (average 90 m) and two holes at Nickel Reward-Vaudeau
- soil sampling
- IP and resistivity surveying of small orientation areas
- heliborne magnetic survey

4. DRILLING PROGRAM (October 1998)

Cored hole MF 10 was drilled in October 1998 to test two targets:

(i) the depth extension of the North Cuni workings below and to the immediate south of previous hole MFP 109 which intersected 5 m 0.4% Ni, 0.5% Cu

(ii) the magnetic and geochemical anomaly defined by surface surveys to the west of the North Cuni workings

MF 10 was drilled to 249.5 m by Almac Drilling Pty Limited from Zeehan. A detailed log of the hole is attached as Appendix A and assays from sawn half-core samples are presented in Appendix B.

The location of the hole is represented on accompanying Maps 2, 3, 4.

Photos of drill core and access development are presented in Appendix C.

On completion, the hole was lined with unslotted PVC casing in the event that future down-hole geophysical surveys might be required.

Core is currently stored on pallets at the Allegiance Core Shed on Main Street in Zeehan.

5. INTERPRETATION and RECOMMENDATIONS

5.1 Interpretation:

MF 10 intersected five gabbro bodies within a sequence of mudstones, siltstones, sandstones and 'gritty' sediments which may have been volcaniclastic.

On the basis of drill hole dips and bedding-to-core axis angles, it can be interpreted that the sediments were dipping east at 55-60°.

The gabbro bodies were generally concordant with the sediments (sills) although several non-conformable contacts were noted (dykes).

As can be seen on the drill hole section (Fig 4), the gabbro bodies in MF 10 do not correlate well with the gabbro positions in MFP 109. this may be due to one or more factors:

(a) mislocation of MFP 109, which was drilled in 1965 and for which records are poor

(b) poddy, discontinuous nature of the gabbros

(c) fault offsetting of the gabbros

Only very minor mineralisation was present in the form of disseminated pyrite in the sediments and gabbros, and pyrite-sphalerite-galena mineralisation in narrow carbonate and quartz-carbonate vein sets cutting both the sediments and gabbros.

No massive or semi-massive Cu-Ni sulfide mineralisation which could be correlated with North Cuni mineralisation was observed in any of the gabbros.

A gabbroic body from 233.5-242.5 m is interpreted as the possible source of the western magnetic-geochemical anomaly. Only minor sulfides in the form of disseminated pyrite and pyrite-sphalerite-galena in carbonate and quartz-carbonate veins was intersected.

The hole was stopped in gritty sediments with a minor gabbroic component. However, the down-dip extension of the surface anomalous zone had been well passed, and this unit is interpreted as typical of the Cambrian formations in this area.

MF 10 is shown on Fig 3 in plan and longitudinal projection formats relative to all other drilling in the North Cuni-Genets Winze area.

The data has been interpreted as representing a series of conformable gabbro sills, strongly folded (or faulted) in the area between North Cuni workings and Genets Winze workings from a N-S striking sequence to a north-east-south-west striking sequence.

Massive Cu-Ni mineralisation has been developed in discontinuous 'pods' within several of these gabbros.

South of the zone of disruption most mineralisation appears concentrated in the central gabbro which hosts the North Cuni workings.

North of the zone of disruption most mineralisation appears concentrated in a more westerly gabbro which hosts the Genets Winze mineralisation.

However, depending on the nature of the zone of disruption, these two mineralised bodies could be part of the same body.

Drilling to date now suggests the known mineralisation may plunge north.

MF 10 may have missed the mineralisation for a combination of the following reasons:

(a) it drilled beneath the north plunging mineralised body (as shown on longitudinal projection)

(b) the gabbro bodies and the accompanying mineralisation are very poddy and discontinuous

(c) mineralisation does not persist in depth

Reason (a) is considered the most probable.

5.2 Recommendations:

The Melba Flats area is still regarded as having high potential for the discovery of high grade Cu-Ni-Au-PGM mineralisation.

Mineralisation is scattered along a four kilometre strike length of potential host rocks, and drilling to date has been very patchy and shallow.

MF 10 was a useful hole in that it tested two targets. However, it in no way represents an adequate test of the target.

Further exploration is justified in the North Cuni-Genets Winze area and in the Nickel Reward-Vaudeau area. In the North Cuni-Genets

Winze area, the following work is recommended:

(a) down-hole EM on MF 10 to test for 'near miss' situations

(b) drilling of a further hole as shown on Fig 3 Longitudinal Projection to test for depth extensions of mineralisation in MF 03 (0.5 m 7.7% Ni, 2.9% Cu) and MFP 110 (3.4 m 4.3% Ni, 2.7% Cu)

In the Nickel Reward-Vaudeau area it is recommended that existing data be thoroughly collated and assessed prior to any further drill testing in that area.

DRILL LOG

COMPANY: Allegiance Mining NL
PROJECT: Melba Flats
HOLE NUMBER: MF 10

Commenced:	26 October 98
Completed:	30 October 98
Logged By:	L A Newnham
Drilled By:	Almac Drilling

Purpose of Hole
.To test both extensions of North Cuni mineralisation and previously untested geochemical and magnetic anomaly west of North Cuni;

Comments on Completion
.a series of gabbroic dykes within a sequence of sandstones, shales and siltstones was intersected as anticipated; however, virtually no mineralisation was intersected; a thick gabbro dyke or sill is interpreted as the source of the western magnetic and geochemical anomaly;

ANALYSIS DESCRIPTION

Job number : BU015389 Order number : L.Newnham drop-off

Scheme code : S033 - Drillcore/Rock; Dry, Jaw crush, Fine pulv, Ring

---

Sample preparation. Drillcore,Rock samples; Dry, Jaw crush, Fine pulverise, Ringmill, <3.5kg

---

Scheme code : F652 - 50g fire assay, Lead collection, AAS

Fire assay, Lead collection, Aqua Regia,Uranyl Nitrate digest, AAS, 50g sample.

Scheme code : G103 - Triple acid digest, Ore Grade samples

Triple acid digest, (HCl,HNO3,HClO4), Ore grade samples.

Scheme code : A103 - AAS analysis

AAS analysis of sample after G103 digest.

REFERENCE

STRATIGRAPHY

Cainozoic	Qra	Marsh and swamp deposits; alluvium; river gravels; talus.
Devonian	Db	Bell Shale (Siltstone).
	Df	Florence Quartzite (Sandstone).
Silurian	Sac	Austral Creek Siltstone (Siltstone).
	Sk	Keel Quartzite (Sandstone).
	Sa	Amber Slate (Siltstone).
	Sc	Crotty Quartzite (Dominantly sandstone with minor siltstone).
Middle Cambrian	€db	Brewery Junction Formation (Interbedded siltstone, sandstone and conglomerate).
	€dra	Razorback Conglomerate (Dominantly chert deriver, interbedded conglomerate, pebbly sandstone and sandstone).
	€dh	Hodge Slate (Interbedded siltstone and mudstone with minor sandstone).
	€dre	Red Lead Conglomerate (Poorly-sorted, volcaniclastic, polymic conglomerate).
Cambrian (?)	€vs	Interbedded black mudstone, red siltstone, grey Volcaniclastic (andesitic) lithicwacke and quartz wacke.
Eocambrian	€cc	Crimson Creek Formation (Volcaniclastic [basaltic] lithicwacke, siltstone and mudstone with intercalated tholeiitic basalt flows).
	€sru	Success Creek group (Dominantly Siltstone).
	€sd	Success Creek group (Dominantly Sandstone).

IGNEOUS ROCKS

Devonian (?)	Dgq	Red and white massive quartz bodies.
Cambrian (?)	€g	Subophitic textured gabbroic rocks.
Cambrian	€sb	Basalt, commonly with pillows and individual flows graded from coarse-grained bases to fine-grained tops.
	€sg	Massive and multiply-intrusive two-pyroxene, granular textured gabbro.
	€spg	Serpentinised peridotite with intrusive gabbro.
	€sp	Serpentinised, orthopyroxene-rich, peridotite.
	€so	Serpentinised, olivine-rich, peridotite.
	€ss	Undifferentiated, massive and foliated, serpentinite.
